LISTVIEW INSERT COLUMN hDlg, id&, col&, StrExpr, ColWidth&, format&
LISTVIEW INSERT ITEM hDlg, id&, item&, image&, StrExpr
LISTVIEW RESET hDlg, id&
LISTVIEW SELECT hDlg, id&, item& [, col&]
LISTVIEW SET COLUMN hDlg, id&, col&, NumExpr
LISTVIEW SET HEADER hDlg, id&, col&, StrExpr
LISTVIEW SET IMAGE hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGE2 hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGELIST hDlg, id&, hLst, NumExpr
LISTVIEW SET MODE hDlg, id&, NumExpr
LISTVIEW SET OVERLAY hDlg, id&, item&, NumExpr
```

LISTVIEW SET STYLEXX ***hDlg, id&, NumExpr***
LISTVIEW SET TEXT ***hDlg, id&, item&, col&, StrExpr***
LISTVIEW SET USER ***hDlg, id&, item&, NumExpr***
LISTVIEW SORT ***hDlg, id&, col&*** **[,** ***options...*****]**
LISTVIEW UNSELECT ***hDlg, id&, item&,*** **[*****col&*****]**
LISTVIEW VISIBLE ***hDlg, id&, item&***

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column

numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable

specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg, id&, col&, StrExpr, ColWidth&, format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&/col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&/col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.
NumExpr defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text

%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg*, *id&*, *item&*, *col&*, *StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and

	delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

```

hDlg	Handle of the dialog that owns the ListView.
hLst	Handle of the ImageList to be used for graphical items.
hLV	Handle of the ListView Control.
id&	The control identifier assigned with CONTROL ADD LISTVIEW.
item&	A data item number. First=1, second=2...
col&	A vertical column number. First=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks

There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0	Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one

item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*)

is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This

special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg*, *id&*, *item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg*, *id&*, *col&*, *NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If

NumExpr is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg, id&, col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.

UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW SET IMAGE2 hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGELIST hDlg, id&, hLst, NumExpr
LISTVIEW SET MODE hDlg, id&, NumExpr
LISTVIEW SET OVERLAY hDlg, id&, item&, NumExpr
LISTVIEW SET STYLEXX hDlg, id&, NumExpr
LISTVIEW SET TEXT hDlg, id&, item&, col&, StrExpr
LISTVIEW SET USER hDlg, id&, item&, NumExpr
LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to

multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which

exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to

facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user

value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg, id&, col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg, id&, item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg, id&, item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW SET OVERLAY hDlg, id&, item&, NumExpr
LISTVIEW SET STYLEXX hDlg, id&, NumExpr
LISTVIEW SET TEXT hDlg, id&, item&, col&, StrExpr
LISTVIEW SET USER hDlg, id&, item&, NumExpr
LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id&	The control identifier assigned with CONTROL ADD LISTVIEW.
item&	A data item number. First=1, second=2...
col&	A vertical column number. First=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks

There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either

dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg*, *id&*, *hLst*, *NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg*, *id&*, *NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg*, *id&*, *item&*, *NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg*, *id&*, *NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker

%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg, id&, col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView

control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW INSERT ITEM hDlg, id&, item&, image&, StrExpr
LISTVIEW RESET hDlg, id&
LISTVIEW SELECT hDlg, id&, item& [, col&]
```

```
LISTVIEW SET COLUMN hDlg, id&, col&, NumExpr
LISTVIEW SET HEADER hDlg, id&, col&, StrExpr
LISTVIEW SET IMAGE hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGE2 hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGELIST hDlg, id&, hLst, NumExpr
LISTVIEW SET MODE hDlg, id&, NumExpr
LISTVIEW SET OVERLAY hDlg, id&, item&, NumExpr
LISTVIEW SET STYLEXX hDlg, id&, NumExpr
LISTVIEW SET TEXT hDlg, id&, item&, col&, StrExpr
LISTVIEW SET USER hDlg, id&, item&, NumExpr
LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the

unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number

(1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg, id&, item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg, id&, col&, StrExpr, ColWidth&, format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&*

specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
% LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode

% LVS_EX_ONECLICKACTIVATE	Notification sent on single click
% LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg*, *id&*, *item&*, *col&*, *StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format:

	, , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon

IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg, id&, col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg, id&, item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is

assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg, id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg, id&, item&, col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg, id&, item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg, id&, col&, StrExpr, ColWidth&, format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for

the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg*, *id&*, *NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg*, *id&*, *item&*, *col&*, *StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe

the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW SET IMAGELIST hDlg, id&, hLst, NumExpr
LISTVIEW SET MODE hDlg, id&, NumExpr
LISTVIEW SET OVERLAY hDlg, id&, item&, NumExpr
LISTVIEW SET STYLEXX hDlg, id&, NumExpr
LISTVIEW SET TEXT hDlg, id&, item&, col&, StrExpr
LISTVIEW SET USER hDlg, id&, item&, NumExpr
LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg	Handle of the dialog that owns the ListView.
hLst	Handle of the ImageList to be used for graphical items.
hLV	Handle of the ListView Control.
id&	The control identifier assigned with CONTROL ADD LISTVIEW.
item&	A data item number. First=1, second=2...
col&	A vertical column number. First=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg, id&, col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg, id&, item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of

the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg, id&, col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg, id&, col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg, id&* TO *hLV, idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg, id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg, id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are

currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted

from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use

LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg, id&, item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW SET IMAGE2 hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGELIST hDlg, id&, hLst, NumExpr
LISTVIEW SET MODE hDlg, id&, NumExpr
LISTVIEW SET OVERLAY hDlg, id&, item&, NumExpr
LISTVIEW SET STYLEXX hDlg, id&, NumExpr
LISTVIEW SET TEXT hDlg, id&, item&, col&, StrExpr
LISTVIEW SET USER hDlg, id&, item&, NumExpr
```

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]
LISTVIEW UNSELECT *hDlg*, *id&*, *item&*, [*col&*]
LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

hDlg	Handle of the dialog that owns the ListView.
hLst	Handle of the ImageList to be used for graphical items.
hLV	Handle of the ListView Control.
id&	The control identifier assigned with CONTROL ADD LISTVIEW.
item&	A data item number. First=1, second=2...
col&	A vertical column number. First=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks

There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0	Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg*, *id&*, *item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg*, *id&*, *col&*, *NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg*, *id&*, *col&*, *StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg*, *id&*, *item&*, *NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg*, *id&*, *item&*, *NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary

image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg*, *id&*, *hLst*, *NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg*, *id&*, *NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg*, *id&*, *item&*, *NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg*, *id&*, *NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text

%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg*, *id&*, *item&*, *col&*, *StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

YYYYDDMM — A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

hDlg	Handle of the dialog that owns the ListView.
hLst	Handle of the ImageList to be used for graphical items.
hLV	Handle of the ListView Control.
id&	The control identifier assigned with CONTROL ADD LISTVIEW.
item&	A data item number. First=1, second=2...
col&	A vertical column number. First=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks

There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0	Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data

item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg*, *id&*, *item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg*, *id&*, *col&*, *NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection

%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg*, *id&*, *item&*, *col&*, *StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string

NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in

each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg, id&, col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg, id&, item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is

found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item& [, col&]*

The string data item specified by *item&/col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&/col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg*, *id&*, *NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg*, *id&*, *item&*, *col&*, *StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

Example

LISTVIEW statement IMPROVED

Purpose Manipulate a LISTVIEW control in order to set/retrieve data.

Syntax

```
LISTVIEW DELETE COLUMN hDlg, id&, col&
LISTVIEW DELETE ITEM hDlg, id&, item&
LISTVIEW FIND hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIT CONTENT hDlg, id&, col&
LISTVIEW FIT HEADER hDlg, id&, col&
LISTVIEW GET COLUMN hDlg, id&, col& TO datav&
LISTVIEW GET COUNT hDlg, id& TO datav&
LISTVIEW GET HEADER hDlg, id&, col& TO txtv$
LISTVIEW GET HEADERID hDlg, id& TO hLV, idv&
LISTVIEW GET MODE hDlg, id& TO datav&
LISTVIEW GET SELCOUNT hDlg, id& TO datav&
LISTVIEW GET SELECT hDlg, id& [, item&] TO datav&
LISTVIEW GET STATE hDlg, id&, item&, col& TO datav&
LISTVIEW GET STYLEXX hDlg, id& TO datav&
LISTVIEW GET TEXT hDlg, id&, item&, col& TO txtv$
LISTVIEW GET USER hDlg, id&, item& TO datav&
LISTVIEW INSERT COLUMN hDlg, id&, col&, StrExpr, ColWidth&, format&
LISTVIEW INSERT ITEM hDlg, id&, item&, image&, StrExpr
LISTVIEW RESET hDlg, id&
LISTVIEW SELECT hDlg, id&, item& [, col&]
LISTVIEW SET COLUMN hDlg, id&, col&, NumExpr
LISTVIEW SET HEADER hDlg, id&, col&, StrExpr
LISTVIEW SET IMAGE hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGE2 hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGELIST hDlg, id&, hLst, NumExpr
LISTVIEW SET MODE hDlg, id&, NumExpr
LISTVIEW SET OVERLAY hDlg, id&, item&, NumExpr
LISTVIEW SET STYLEXX hDlg, id&, NumExpr
LISTVIEW SET TEXT hDlg, id&, item&, col&, StrExpr
LISTVIEW SET USER hDlg, id&, item&, NumExpr
LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg	Handle of the dialog that owns the ListView.
hLst	Handle of the ImageList to be used for graphical items.
hLV	Handle of the ListView Control.
id&	The control identifier assigned with CONTROL ADD LISTVIEW.
item&	A data item number. First=1, second=2...
col&	A vertical column number. First=1, second=2...
NumExpr	A expression passed as a parameter.

StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks

There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0	Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg, id&, col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg, id&, item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins

with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg, id&, col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg, id&, col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg, id&* TO *hLV, idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg, id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not

a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg*, *id&*, *item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg*, *id&*, *col&*, *NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg*, *id&*, *col&*, *StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg*, *id&*, *item&*, *NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg*, *id&*, *item&*, *NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg*, *id&*, *hLst*, *NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons

%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the

optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg, id&, item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg	Handle of the dialog that owns the ListView.
hLst	Handle of the ImageList to be used for graphical items.
hLV	Handle of the ListView Control.
id&	The control identifier assigned with CONTROL ADD LISTVIEW.
item&	A data item number. First=1, second=2...
col&	A vertical column number. First=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks

There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0	Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column

numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable

specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg, id&, col&, StrExpr, ColWidth&, format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&/col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&/col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text

%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg*, *id&*, *item&*, *col&*, *StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and

	delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg, id&, item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg, id&, item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one

item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*)

is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXXX. This

special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg*, *id&*, *item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg*, *id&*, *col&*, *NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If

NumExpr is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg, id&, col&* [, *options...*]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.

UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW SET TEXT hDlg, id&, item&, col&, StrExpr
LISTVIEW SET USER hDlg, id&, item&, NumExpr
LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to

	multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which

exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg, id&, col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg, id&, col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg, id&* TO *hLV, idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg, id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg, id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg, id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to

facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg*, *id&*, *item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg*, *id&*, *col&*, *NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg*, *id&*, *col&*, *StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg*, *id&*, *item&*, *NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg*, *id&*, *item&*, *NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg*, *id&*, *hLst*, *NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg*, *id&*, *NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user

value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

Example

LISTVIEW statement IMPROVED

Purpose Manipulate a LISTVIEW control in order to set/retrieve data.

Syntax

```
LISTVIEW DELETE COLUMN hDlg, id&, col&
LISTVIEW DELETE ITEM hDlg, id&, item&
LISTVIEW FIND hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIT CONTENT hDlg, id&, col&
LISTVIEW FIT HEADER hDlg, id&, col&
LISTVIEW GET COLUMN hDlg, id&, col& TO datav&
LISTVIEW GET COUNT hDlg, id& TO datav&
LISTVIEW GET HEADER hDlg, id&, col& TO txtv$
LISTVIEW GET HEADERID hDlg, id& TO hLV, idv&
LISTVIEW GET MODE hDlg, id& TO datav&
LISTVIEW GET SELCOUNT hDlg, id& TO datav&
LISTVIEW GET SELECT hDlg, id& [, item&] TO datav&
LISTVIEW GET STATE hDlg, id&, item&, col& TO datav&
LISTVIEW GET STYLEXX hDlg, id& TO datav&
LISTVIEW GET TEXT hDlg, id&, item&, col& TO txtv$
LISTVIEW GET USER hDlg, id&, item& TO datav&
LISTVIEW INSERT COLUMN hDlg, id&, col&, StrExpr, ColWidth&, format&
LISTVIEW INSERT ITEM hDlg, id&, item&, image&, StrExpr
LISTVIEW RESET hDlg, id&
LISTVIEW SELECT hDlg, id&, item& [, col&]
LISTVIEW SET COLUMN hDlg, id&, col&, NumExpr
LISTVIEW SET HEADER hDlg, id&, col&, StrExpr
LISTVIEW SET IMAGE hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGE2 hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGELIST hDlg, id&, hLst, NumExpr
LISTVIEW SET MODE hDlg, id&, NumExpr
LISTVIEW SET OVERLAY hDlg, id&, item&, NumExpr
LISTVIEW SET STYLEXX hDlg, id&, NumExpr
LISTVIEW SET TEXT hDlg, id&, item&, col&, StrExpr
LISTVIEW SET USER hDlg, id&, item&, NumExpr
LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id&	The [control identifier]() assigned with [CONTROL ADD LISTVIEW]().
item&	A data item number. First=1, second=2...
col&	A vertical column number. First=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A [string expression]() passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A [long integer]() variable to which result data is assigned.

Remarks

There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control [style]() parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with [header]() text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard [LISTBOX]() control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg, id&, col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg, id&, col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg, id&* TO *hLV, idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either

dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg*, *id&*, *hLst*, *NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg*, *id&*, *NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg*, *id&*, *item&*, *NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg*, *id&*, *NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker

%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg, id&, col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView

control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

See also Dynamic Dialog Tools, CONTROL ADD LISTVIEW, CONTROL SET COLOR, CONTROL SET FONT, HEADER, IMAGELIST

LO function

LO function

Purpose Extract the least significant (low-order) portion of an value.

Syntax `result = LO(DataType, value)`

Remarks The value returned by LO is unsigned if *DataType* is BYTE, WORD, or DWORD, and signed if *DataType* is INTEGER or LONG. *value* may be up to twice the size of the data type specified by *DataType*. In the following example, *n* may be up to a 16-bit value (twice the size of a BYTE):

```
b = LO(BYTE,n)
```

Restrictions LO replaces LOBYT, LOWRD, and LOINT. Note that those functions are no longer supported, so update your code to use the new syntax.

See also HI, MAK

LOC function

LOC function

Purpose Determine the current seek position in an open disk file.

Syntax `qResult&& = LOC([#] filenum&)`

Remarks LOC is provided for compatibility with older BASICs. It is recommended that code is modified to use the SEEK function instead. The Number symbol (#) is optional, but recommended for clarity.

See also FILEATTR, SEEK function, SEEK statement

LOCAL statement

LOCAL statement

Purpose Declare local variables inside a Sub, Function, Method, or Property. Local variables retain their values only until the end of the procedure.

Syntax
```
LOCAL variable[()] [AS type] [, variable[()]] [...]
LOCAL variable[()] [, variable[()]] [, ...] AS type
```

Remarks The LOCAL statement is valid only inside a Sub, Function, Method, or Property. Local variables lose their values when the procedure ends. Storage space for local variables is allocated on the stack, and each local variable is initialized to zero (or, for

variables, an empty string) each time the enclosing procedure is called.

To declare an array as a local variable, use an empty set of parentheses in the variable list: You can then use the DIM statement to dimension the array.

```
LOCAL MyArray%()
LOCAL StringArray() AS STRING
```

The LOCAL statement may, optionally, accept a list of variables, all of which are defined by the type descriptor keyword that follows them. For example:

```
LOCAL aaa, bbb, ccc AS INTEGER
LOCAL vptr, aptr() AS LONG PTR
```

Restrictions DEF*type* has no effect on variables defined by a LOCAL statement.

See also DIM, GLOBAL, INSTANCE, STATIC, THREADED

Example
```
Test% = 100
ShowText "Before: " + STR$(Test%)
CALL Locals
ShowText "After:  " + STR$(Test%)

SUB Locals
  LOCAL Test%
  Test% = 0
  ShowText "In SUB: " + STR$(Test%)
END SUB
```

Result
```
Before:  100
In SUB:    0
After:   100
```

LOCK statement

LOCK statement

Purpose Lock part or all of an open file, to prevent other processes from accessing it.

Syntax
```
LOCK [#] filenum& [, {record&& | startbyte&& TO endbyte&&}]
```

Remarks LOCK prevents another process from accessing a record, range of records, byte, or range of bytes in a file opened as file number *filenum&*.

If the file was opened in random-access mode, *record&&*, *startbyte&&*, and *endbyte&&* specify record numbers. When used with binary mode files, *record&&*, *startbyte&&*, and *endbyte&&* specify byte positions, starting from either zero or one (the default).

If a record is specified, only that record (or byte) is locked. Otherwise, a range of records (or bytes) is locked, from *startbyte&&* to *endbyte&&*.

If no records are specified, or if the file was opened in sequential mode, the entire file is locked.

All records (or bytes) to be locked must be subsequently unlocked using the UNLOCK statement. Multiple locks may be placed on a file, and locks may be unlocked in any order. However, the parameters used for each UNLOCK statement must exactly match those used for the previous corresponding LOCK statement.

All locked records (or bytes) must be unlocked using the UNLOCK statement

before the file can be closed.

If a lock attempt fails, PowerBASIC sets the ERR system variable to reflect a run-time Error 70 ("Permission denied"), or Error 75 ("Path/file access error").

See also OPEN, UNLOCK

Example

```
OPEN "PATIENTS.DAT" FOR RANDOM AS #1 LEN = 1024
' determine the record number to retrieve
LOCK #1, recnum
GET #1, recnum
' process the record here
PUT #1, recnum
UNLOCK #1, recnum
CLOSE #1
```

LOF function

LOF function

Purpose Return the length of an open disk file.

Syntax ***y&&*** **= LOF([#]** ***filenum&*****)**

Remarks *filenum&* is the file number with which the file was opened. LOF returns the size of the indicated file in bytes, in the Quad-integer range 0 to 2^63-1. The Number symbol (#) is optional, but recommended for clarity.

See also FILEATTR, LOC, SEEK function, SEEK statement

Example

```
OPEN "RECIPES.DAT" FOR BINARY AS #1
x&& = LOF(1)
CLOSE #1
```

LOG function

LOG, LOG2 and LOG10 functions

Purpose LOG returns the natural (base *e*) logarithm of its argument. LOG2 returns the base 2 logarithm. LOG10 returns the common (base 10) logarithm.

Syntax

y **= LOG(*****numeric_expression*****)**
y **= LOG2(*****numeric_expression*****)**
y **= LOG10(*****numeric_expression*****)**

Remarks A logarithm of a number is the power to which the base would have to be raised to yield the number. Thus:

```
logarithm (base b) of n = x  if  b^x = n
```

and:

```
(base)^log(n) = n
```

The EXP functions complement the LOG functions. For example, if `s = LOG(t)`, then `t = EXP(s)`.

By definition, the logarithm (any base) of 1 is 0. LOG returns the natural logarithm (base *e*, where *e* = 2.718282...) of its argument. LOG2 and LOG10 return the logarithm for base 2 and 10, respectively.

numeric_expression must be a value greater than zero.

LOG, LOG2, and LOG10 return Extended-precision values.

See also EXP, EXP2, EXP10, SQR, Arithmetic Operators

LOG2 function

LOG, LOG2 and LOG10 functions

Purpose LOG returns the natural (base *e*) logarithm of its argument. LOG2 returns the base 2 logarithm. LOG10 returns the common (base 10) logarithm.

Syntax

```
y = LOG(numeric_expression)
y = LOG2(numeric_expression)
y = LOG10(numeric_expression)
```

Remarks A logarithm of a number is the power to which the base would have to be raised to yield the number. Thus:

```
logarithm (base b) of n = x  if  b^x = n
```

and:

```
(base)^log(n) = n
```

The EXP functions complement the LOG functions. For example, if `s = LOG(t)`, then `t = EXP(s)`.

By definition, the logarithm (any base) of 1 is 0. LOG returns the natural logarithm (base *e*, where *e* = 2.718282...) of its argument. LOG2 and LOG10 return the logarithm for base 2 and 10, respectively.

numeric_expression must be a value greater than zero.

LOG, LOG2, and LOG10 return Extended-precision values.

See also EXP, EXP2, EXP10, SQR, Arithmetic Operators

LOG10 function

LOG, LOG2 and LOG10 functions

Purpose LOG returns the natural (base *e*) logarithm of its argument. LOG2 returns the base 2 logarithm. LOG10 returns the common (base 10) logarithm.

Syntax

```
y = LOG(numeric_expression)
y = LOG2(numeric_expression)
y = LOG10(numeric_expression)
```

Remarks A logarithm of a number is the power to which the base would have to be raised to yield the number. Thus:

```
logarithm (base b) of n = x  if  b^x = n
```

and:

```
(base)^log(n) = n
```

The EXP functions complement the LOG functions. For example, if `s = LOG(t)`, then `t = EXP(s)`.

By definition, the logarithm (any base) of 1 is 0. LOG returns the natural logarithm (base *e*, where *e* = 2.718282...) of its argument. LOG2 and LOG10 return the logarithm for base 2 and 10, respectively.

numeric_expression must be a value greater than zero.

LOG, LOG2, and LOG10 return Extended-precision values.

See also EXP, EXP2, EXP10, SQR, Arithmetic Operators

LPRINT statement

LPRINT statement

Purpose Output (device-dependent) text and data to a printer device.

Syntax `LPRINT [expression] [SPC(n)] [TAB(n)] [,] [;]`

Remarks The LPRINT functionality is identical to the traditional PRINT statement, except that the data is sent directly to a line printer rather than to a display. A line printer is one which will accept standard ASCII text and associated control codes, such as $CR, $LF, and $FF.

PowerBASIC inserts a carriage return and linefeed at the end of each printed line. A semi-colon between expressions is an optional delimiter which leaves the printer column position unchanged. A comma moves the printer position to the next column of 14 positions each. A trailing semi-colon suppresses the final CR/LF. If TAB(n) is less than the current printer position, output is placed at the requested position on the following line.

Before you execute an LPRINT statement, you must explicitly connect to the intended line printer using the LPRINT ATTACH statement. If the connection to the device is unsuccessful, all LPRINT statements are ignored until a valid printer device has been attached. LPRINT communicates directly with the attached device, bypassing the Windows operating system and printer driver. Therefore, any settings such as "work offline" in your printer properties dialog will be ignored.

Once all the data has been sent to the printer, detach the printer so other applications can use it., with the LPRINT CLOSE statement

Host-based (Windows-only) printers use proprietary control protocols so, sending print data to them with LPRINT is unlikely to produce any output at all. PowerBASIC supports host-based printers through

and related statements.

See also LPRINT ATTACH, LPRINT CLOSE, LPRINT FLUSH, LPRINT FORMFEED, LPRINT$, XPRINT, XPRINT ATTACH

Example

```
' Typical LPRINT printing strategy
ERRCLEAR
LPRINT ATTACH "LPT2"    ' Use LPT2 device
IF ISFALSE ERR AND ISTRUE LEN(LPRINT$) THEN
  LPRINT "This is your line-printer talking"
  LPRINT FORMFEED       ' Issue a formfeed
  LPRINT FLUSH          ' flush the buffer
  LPRINT CLOSE          ' detach the printer
END IF
```

LPRINT ATTACH statement

LPRINT ATTACH statement

Purpose Connect to a line-printer device for use with LPRINT.

Syntax `LPRINT ATTACH device$`

Remarks LPRINT ATTACH attempts a direct connection to the specified [line] printer device. A line printer is one that will accept standard ASCII text and any device-specific control codes, such as CR, LF, and FF.

A line printer is named by the port to which it is attached (LPT1, etc.) because the data is sent directly to the port, not through a device driver. That is, LPRINT communicates directly with the attached line printer device, bypassing the spooler and printer driver. Therefore, any settings such as "work offline" in the Printer Properties dialog will be ignored.

Once the printer is attached by LPRINT ATTACH, print data can be sent to it with the LPRINT statement.

LPRINT ATTACH allows you to change the printer device used by LPRINT operation. When executed, the current connection (if any) is closed and the new connection is established. No colon is used in the device name. For example, to connect to *LPT2:*

```
LPRINT ATTACH "LPT2"
```

or to a printer on a network server:

```
LPRINT ATTACH "\\SERVER\HPLJ5"
```

*device$* must be a valid device name and cannot exceed 32 characters in length. In some circumstances, such as with the Novell network client, LPRINT ATTACH with a UNC name may be rejected, and the LPRINT ATTACH will be unsuccessful, and a subsequent LPRINT$ test will return an empty string.

If LPRINT ATTACH is not successful, an Error 68 ("Device unavailable") is generated and LPRINT$ returns a nul (empty)

. If no LPRINT ATTACH is ever executed (successful or not), PowerBASIC will attempt to connect to the line printer at LPT1. Once any LPRINT ATTACH is attempted, no default to LPT1 will be presumed.

Care must be used with line printers in Windows, since if there is no available printer attached to the port, program execution may be suspended, with no errors. So, it is wise to use LPRINT ATTACH to explicitly connect the intended printer device, and test for the successful connection by the examination of LPRINT$ and ERR. For example:

```
ERRCLEAR
LPRINT ATTACH "LPT3"
IF ERR OR LPRINT$ = "" THEN PRINT "Connection failed"
```

Once all the data has been sent to the printer, detach the printer so other applications can use it., with the LPRINT CLOSE statement

Note: The Win32 API call *EnumPrinters* can give you a list of all valid printers and print devices, or you can enumerate the list of printers with the PRINTERCOUNT and PRINTER$ functions.

Restrictions If *device$* is an empty string, the current connection (if any) is detached. This is equivalent to the LPRINT CLOSE statement.

See also LPRINT, LPRINT CLOSE, LPRINT FLUSH, LPRINT FORMFEED, LPRINT$, XPRINT, XPRINT ATTACH

Example

```
' Typical LPRINT printing strategy
ERRCLEAR
LPRINT ATTACH "LPT2" ' Use LPT2 device
IF (ERR<>0) OR (LEN(LPRINT$)) THEN
  LPRINT "This is your line-printer talking"
  LPRINT FORMFEED      ' Issue a formfeed
  LPRINT FLUSH         ' flush the buffer
  LPRINT CLOSE     ' detach the printer
END IF
```

LPRINT CLOSE statement

LPRINT CLOSE statement

Purpose Disconnect the current printer device.

Syntax `LPRINT CLOSE`

Remarks LPRINT CLOSE detaches the currently selected printer connection (established with the

LPRINT ATTACH statement) from LPRINT operations, allowing the spooler subsystem to commence print operations. Once a connection is closed, LPRINT$ will return an empty printer device name string until a new connection is established.

LPRINT CLOSE is equivalent to using LPRINT ATTACH with an empty printer device name string.

Restrictions LPRINT CLOSE is an essential step in the print process. To ensure the printer device is available to other applications, printers should always be closed when not in use. Failing to close a connection may cause significant delays before printing commences. In some cases, some or all of the print data may be lost.

See also LPRINT, LPRINT ATTACH, LPRINT FLUSH, LPRINT FORMFEED, LPRINT$, XPRINT, XPRINT ATTACH

Example

```
' Typical LPRINT printing strategy
ERRCLEAR
LPRINT ATTACH "LPT2" ' Use LPT2 device
IF ISTRUE ERR OR ISFALSE LEN(LPRINT$) THEN
  LPRINT "This is your line-printer talking"
  LPRINT FORMFEED      ' Issue a formfeed
  LPRINT FLUSH         ' flush the buffer
  LPRINT CLOSE     ' detach the printer
END IF
```

LPRINT FLUSH statement

LPRINT FLUSH statement

Purpose Flush any remaining print data to a printer device and signal the start of the print process.

Syntax `LPRINT FLUSH`

Remarks LPRINT FLUSH forces the operating system to flush any buffered data and begin printing. Use LPRINT FLUSH to ensure print data is submitted to the printer as soon as possible, rather than waiting for any timeout period to elapse first. Depending upon the printer and its drivers, printing may begin immediately, or it may be delayed until execution of an LPRINT CLOSE statement.

Typically, an LPRINT FLUSH statement is preceded with a FORMFEED statement, so ensure that the print job is ejected normally from the printer device.

See also LPRINT, LPRINT ATTACH, LPRINT CLOSE, LPRINT FORMFEED, LPRINT$, XPRINT, XPRINT ATTACH

Example

```
' Typical LPRINT printing strategy
ERRCLEAR
LPRINT ATTACH "LPT2" ' Use LPT2 device
IF ISTRUE ERR OR ISFALSE LEN(LPRINT$) THEN
  LPRINT "This is your line-printer talking"
  LPRINT FORMFEED      ' Issue a formfeed
  LPRINT FLUSH         ' flush the buffer
  LPRINT CLOSE     ' detach the printer
END IF
```

LPRINT FORMFEED statement

LPRINT FORMFEED statement

Purpose Send a formfeed (page eject) character to an attached printer device.

Syntax `LPRINT FORMFEED`

Remarks For direct connections, LPRINT FORMFEED sends a form-feed character (ASCII character 12, $FF, or CHR$(12)) to the attached line printer device, to ensure the current page will be ejected. For host-based connections, PowerBASIC signals to the printing subsystem to perform the page eject operation.

Typically, an LPRINT FORMFEED is performed before a LPRINT FLUSH and LPRINT CLOSE.

See also LPRINT, LPRINT ATTACH, LPRINT CLOSE, LPRINT FLUSH, LPRINT$, XPRINT, XPRINT ATTACH

Example

```
' Typical LPRINT printing strategy
ERRCLEAR
LPRINT ATTACH "LPT2" ' Use LPT2 device
IF ISTRUE ERR OR ISFALSE LEN(LPRINT$) THEN
  LPRINT "This is your line-printer talking"
  LPRINT FORMFEED      ' Issue a formfeed
  LPRINT FLUSH         ' flush the buffer
  LPRINT CLOSE     ' detach the printer
END IF
```

LPRINT$ function

LPRINT$ function

Purpose Return the name of the printer device used for

operations.

Syntax `device$ = LPRINT$`

Remarks LPRINT$ returns the name of the currently attached printer device used by the LPRINT statement. If there is no attached device, an empty

is returned.

LPRINT$ is primarily used to detect if an LPRINT ATTACH operation was successful.

See also LPRINT, LPRINT ATTACH, LPRINT CLOSE, LPRINT FLUSH, LPRINT FORMFEED, XPRINT, XPRINT ATTACH

Example

```
ERRCLEAR
LPRINT ATTACH "LPT3"
IF ERR <> 0 OR LPRINT$ = "" THEN PRINT "Printer connection failed"
```

LSET statement

LSET statement

Purpose Left-align a

within the space of another string or User-Defined Type.

Syntax `LSET [ABS] result_var = string_expression [USING ustring_expression]`

Remarks LSET left-aligns a string into the space of another string or variable of a User-Defined Type.

ABS If ABS is specified, or *ustring_expression* is null (empty), LSET leaves the padding positions unchanged from their original content, rather than replacing them with spaces.

USING If *string_expression* is shorter then *result_var*, LSET left-justifies *string_expression* within *result_var,* and pads remaining character positions on the right side using the first character in *ustring_expression* or spaces if not specified or is null (empty).

If *string_expression* is longer than *result_var*, LSET truncates *string_expression* from the right until it fits in *result_var*.

LSET can be used to assign the content of a User-Defined Type to a User-Defined Type variable of a different class, or assign a dynamic string to a User-Defined Type. For example:

```
LSET MyType = STRING$(LEN(MyType), 0)
LSET MyType = a$
```

RSET works similarly, but performs right-justification; CSET performs center-justification.

See also CSET, CSET$, GET, LET, LET (with Types), LSET$, PUT, RESET, RSET, RSET$, STRINSERT$, TYPE SET

Example

```
a$ = "SuperBASIC=SuperBASIC"
LSET ABS a$ = "PowerBASIC"
' result: "PowerBASIC=SuperBASIC"

LSET a$ = "PowerBASIC" USING "*"
' result: "PowerBASIC***********"
```

LSET$ function

LSET$ function

Purpose Return a

containing a left-justified (padded) string.

Syntax ***result_var* = LSET$(*string_expression*, *strlen&* [USING *ustring_expression*])**

Remarks LSET$ left-aligns the string *string_expression* into a string of *strlen&* characters.

USING If *ustring_expression* is null (empty) or is not specified, LSET$ pads *string_expression* with space characters. Otherwise, LSET$ pads the string with the first character of *ustring_expression*.

If *string_expression* is shorter then *strlen&*, LSET$ left-justifies *string_expression* within *result_var,* padding the right side as described above; otherwise, LSET$ returns the left-most *strlen&* bytes of *string_expression*.

See also CSET, CSET$, GET, LET, LSET, PUT, RESET, RSET, RSET$, STRINSERT$, TYPE SET

Example

```
a$ = LSET$("PowerBASIC", 20)
' result: "PowerBASIC          "

a$ = LSET$("PowerBASIC",20 USING "*")
' result: "PowerBASIC**********"
```

LTRIM$ function

LTRIM$ function

Purpose Return a copy of a

, with leading characters or strings removed.

Syntax ***x$* = LTRIM$(*MainString* [, [ANY] *MatchString*])**

Remarks *MainString* is the string expression from which to remove characters, and *MatchString* is the string expression containing the characters to remove.

If *MatchString* is not specified, LTRIM$ removes leading spaces. LTRIM$ returns a sub-string of *MainString*, from the first non-*MatchString* (or non-space) to the end of the string. If *MatchString* (or a space) is not present at the beginning of *MainString*, all of *MainString* is returned.

If the ANY keyword is included, *MatchString* specifies a list of single characters to be searched for individually. A match on any one of these as a leading character will cause the character to be removed from the result.

LTRIM$ is case sensitive.

See also CLIP$, EXTRACT$, INSTR, LEFT$, MID$, REMOVE$, REPLACE, RIGHT$, RTRIM$, SHRINK$, STRDELETE$, STRINSERT$, STRREVERSE$, TALLY, TRIM$, UNWRAP$, VERIFY

Example

```
A$ = "0123ABC3210"
A$ = LTRIM$(A$, ANY "0123456789")
```

Result

```
ABC3210
```

MACRO/END MACRO block

MACRO/END MACRO block

Purpose Define a single or multi-line text substitution block.

Syntax

Single line macro:

```
MACRO macroname [(prm1, prm2, ...)] = replacementtext
```

Multi-line macro:

```
MACRO macroname [(prm1, prm2, ...)]
  [MACROTEMP ident1 [, ident2, ...]]
  DIM ident1 AS type [, ident2 AS type, ...]]
  {replacementtext}
  [EXIT MACRO]
  {replacementtext}
END MACRO
```

Macro function:

```
MACRO FUNCTION macroname [(prm1, prm2, ...)]
  [MACROTEMP ident1 [, ident2, ...]
  DIM ident1 AS type [, ident2 AS type, ...]]
  {replacementtext}
  [EXIT MACRO]
  {replacementtext}
END MACRO = returnexpression
```

Remarks Macro is a powerful text substitution construct that may take a single-line or multi-line format. It generates absolutely no executable code unless it is referenced, and effectively allows the programmer to design a part of the PowerBASIC language to his/her own needs and requirements. For example, a simple single-line macro can allow PowerBASIC to emulate the CONST syntax used in Visual Basic - see the box-out below for more information.

A macro must always be defined before it is referenced, and the parameter count must always match the definition. When a macro is referenced, the occurrence of the name is replaced by the defined replacement text, expanded with parameter substitution. The first line of a MACRO definition is termed the macro prototype, and this line may not be split into multiple logical lines with the underscore (_) line continuation character. Likewise, the END MACRO = *returnexpression* may not be split with underscores either. A Macro also cannot end with a line continuation character.

Macros may be nested, and may forward-reference other macros. However, care should be exercised to avoid circular references.

A single-line macro or a macro function may be referenced at any source code position which, when expanded, will be syntactically correct (also see the Restrictions section below). Consider the following simplistic example:

```
MACRO concatenate(prm1,prm2) = prm1 & $SPC & prm2
' more code here
A$ = concatenate("Hello","World")
```

During compilation, PowerBASIC would internally expand this code to become:

```
A$ = "Hello" & $SPC & "World"
```

A multi-line macro, while more powerful in terms of coding, may be referenced only in the "statement" position, which is the first position on a line. That single reference is internally expanded into multiple lines of inline code to perform a complex task. For example:

```
MACRO Display6times(prm1)
  CALL Display(prm1) : CALL Display(prm1)
  CALL Display(prm1) : CALL Display(prm1)
  CALL Display(prm1) : CALL Display(prm1)
END MACRO
' more code here
Display6times("This is very cool...")
```

The single-line MACRO offers a cunning way to retain the CONST syntax used in MSBASIC and Visual Basic in your PowerBASIC code, while maintaining the low overhead advantage of PowerBASIC. For example:

```
MACRO CONST = MACRO
' more code here
CONST Version  = 1&
CONST AppTitle = "My Application"
' more code here
a$ = AppTitle & " v" & FORMAT$(Version)
```

During compilation, the CONST keyword is replaced by the MACRO keyword, dynamically creating a new macro that, in turn, defines a numeric or string literal. When the real macro name is referenced in the code, the literal is substituted directly.

MACROTEMP The MACROTEMP statement may be used to specify a list of one or more identifiers, each of which is automatically made unique to each expansion of a multi-line macro. This is done by internally appending the digits 0001, 0002, etc, to the identifier upon each expansion of the macro.

A text identifier may represent a variable, label, or any other word, which expands appropriately to avoid a duplicate name conflict in your code.

MACROTEMP just creates a symbol name. If this symbol is a variable name, the variable must still be formally declared with an appropriate DIM (or LOCAL) statement. For example:

```
MACRO CopyUntilNul(ptr1,ptr2)
  MACROTEMP LoopPoint, ByteVar
  DIM ByteVar AS BYTE
LoopPoint:
  ByteVar = @ptr1
  @ptr2 = ByteVar
  INCR ptr1
  INCR ptr2
  IF ByteVar <> 0 THEN LoopPoint
END MACRO
```

Using that MACRO definition, the code "CopyUntilNul(Source, Dest)" would expand to something like this:

```
DIM ByteVar0001 AS BYTE
LoopPoint0001:
  ByteVar0001 = @Source
  @Dest = ByteVar0001
  INCR Source
```

```
INCR Dest
IF ByteVar0001 <> 0 THEN LoopPoint0001
```

If the MACROTEMP statement were not used, serious naming conflicts would occur most any time that a macro was expanded more than once in a program. MACROTEMP statements may appear 0, 1, or more times in a macro definition, but they must always precede any other text in the macro.

MACROTEMP statements should be used with any label in a macro that may be expanded more than once in a program, and with any variable that should not be shared with any other expansion of the macro.

EXIT MACRO — EXIT MACRO may be used to terminate execution of code in the current macro expansion. It is functionally identical to the *imaginary* concept of GOTO END-MACRO.

END MACRO — A macro function block can return a value with the END MACRO = *returnexpression* statement.

Restrictions — A macro definition may contain replacement text up to approximately 4000 characters. Macros may specify up to 240 parameters, which may occupy up to approximately 2000 bytes total expanded space per macro.

Macro Function substitutions are limited to an expanded total of approximately 16000 characters per line of original source code.

Macro parameters are substituted directly, so whitespace characters in the passed macro parameters may cause unexpected problems if the expanded code is syntactically incorrect with the additional whitespace. For example, this can be important when specifying UDT variables as macro parameters. Consider the following code:

```
TYPE MyType
  lCount AS LONG
  szText AS ASCIIZ * 256
END TYPE

MACRO PresetUDT(u)
  u.lCount = 1
  u.szText = SPACE$(256)
END MACRO

FUNCTION PBMAIN
  DIM x AS MyType
  PresetUDT(x)
  PresetUDT(x )  ' This line causes an Error 526
END FUNCTION
```

In the code above, the second macro expansion fails to compile because the trailing space in the passed macro parameter becomes part of the expanded code. In this situation, this additional space character breaks the syntax of the UDT variable reference within the expanded macro, triggering a compile-time Error 526 ("Period not allowed"). If we examine how the two expanded macro statements would appear, the problem becomes immediately obvious:

```
x .lCount = 1
 ^
x .szText = SPACE$(256)
 ^
```

(Please note that the caret symbols (^) above have been added purely to illustrate the exact position of the problem)

When using single-line macros that contain numeric expressions, use parentheses around the macro body to guard against unexpected order of precedence problems when the macro is used within an expression. For example, consider the following macro and expansion:

```
MACRO Calculate(p1, p2, p3) = (p1 * p2) \ p3
' more code here
```

```
x = Calculate(a,b,c) ^ 3
```

When this macro is expanded, the expression would be calculated as follows:

```
x = (a * b) \ c ^ 3
```

However, if the macro body was enclosed in parentheses:

```
MACRO Calculate(p1, p2, p3) = ((p1 * p2) \ p3)
```

…then the expanded expression would be calculated thus:

```
x = ((a * b) \ c) ^ 3
```

MACRO prototypes (those beginning with the MACRO keyword) and END MACRO = *returnexpression* lines must be constructed on a single line of source code. That is, they may not be split across multiple lines of source code with line continuation characters, since these interfere with the text substitution process. For example, the following prototype is invalid:

```
MACRO FUNCTION MyMacro1(sParam1, sParam2, sParam3, sParam4)
```

If a macro expands directly to a Function call, the macro can be called using the SUB-style syntax, automatically discarding the function return value. For example:

```
MACRO sm(Msg) = SendMessage(a, Msg, b, c)
```

…can be called like this (if the return value is not required):

```
sm(x)
```

A macro cannot expand directly to a REMark, because REM and ' are processed before the macro is assigned. So, MACRO hello = REM winds up as an invalid, blank macro.

Finally, it should be noted that the Integrated Debugger appears to step over macro references as if they were conventional BASIC statements. This occurs because macro expansion takes place during the compilation process and the original source code is not affected or altered by the compile-time expansion.

See also EXIT, FUNCTION/END FUNCTION, METHOD, PROPERTY, SUB/END SUB

Example

```
' Single-line macro:
MACRO muldivide(p1, p2, p3) = ((p1 * p2) / p3)
' more code here
x = muldivide(3,3,2) + 10

' Multi-line macro and macro function example:
MACRO FUNCTION HowDidIGetHere
  MACROTEMP i, a
  DIM i AS LONG, a$
  FOR i = CALLSTKCOUNT TO 1 STEP -1
    A$ = A$ + CALLSTK$(i) + ", "
  NEXT
END MACRO = RTRIM$(A$, ANY ", ")

MACRO DisplayText(txt)
  #IF %DEF(%PB_CC32)
     PRINT txt
  #ELSE
     MSGBOX txt
  #ENDIF
END MACRO

SUB Testing2(r AS LONG,z AS ASCIIZ)
  DisplayText(HowDidIGetHere)
END SUB

SUB testing1(z AS ASCIIZ)
  DisplayText(HowDidIGetHere)
  CALL Testing2(1,z)
END SUB
```

```
FUNCTION PBMAIN
  DisplayText(HowDidIGetHere)
  CALL Testing1("This is a test")
END FUNCTION

' Useful Macro functions
MACRO Pi = 3.141592653589793##
MACRO DegreesToRadians(dpDegrees) = (dpDegrees * 0.0174532925199433##)
MACRO RadiansToDegrees(dpRadians) = (dpRadians * 57.29577951308232##)
```

MAK function

MAK function

Purpose Create an

value of a specified data type.

Syntax ***resultvar*** **= MAK(*datatype*, *lowderval*, *highorderval*)**

Remarks Create an integral class value of a specified data type (WORD, DWORD,

, INTEGER, LONG, QUAD) from a low-order and a high-order part.

The complements to this function are the HI and LO functions, which may be used to split a single 32-bit value into two 16-bit components.

Restrictions MAK supercedes the MAKWRD, MAKDWD, and MAKPTR functions. Those functions are no longer supported, so update your code to use the new syntax.

See also HI, LO

Example

```
dwResult = MAK(DWORD, x??, y??)
```

MAT statement

MAT statement

Purpose To simplify Matrix Algebra calculations.

Syntax

```
MAT a1() = CON              'Set all elements of a1() to one
MAT a1() = CON(expr)        'Set all elements of a1() to value of expr
MAT a1() = IDN              'Establish a1() as an identity matrix
MAT a1() = ZER              'Set all elements of a1() to zero
MAT a1() = a2() + a3()      'Addition
MAT a1() = a2()             'Assignment
MAT a1() = INV(a2())        'Inversion
MAT a1() = (expr) * a2()    'Scalar Multiplication
MAT a1() = a2() - a3()      'Subtraction
MAT a1() = a2() * a3()      'Multiplication
MAT a1() = TRN(a2())        'Transposition
```

Remarks Array names with the MAT statements may optionally include a set of empty parentheses. The following are both equally valid, but the inclusion of the parentheses improves clarity of the code:

```
MAT a1 = CON
MAT a1() = CON
```

MAT CON, IDN ZER + - = and TRN operations are valid with Byte, Word, Double-word, Integer, Long-integer, Quad-integer, Single-precision, Double-precision and Extended-precision arrays.

Matrix * and INV operations support all

types.

It is the programmer's responsibility to ensure that arrays used with MAT are of the appropriate size and type. All operations involving two or more arrays require that they be of exactly the same size and type, without exception. Failure to adhere causes undefined results. In the interest of execution speed, no error checking is performed at run-time.

Every scalar value denoted here as *'expr'* must be enclosed in parentheses. Although Matrix operations tend to imply a two-dimensional array, unless otherwise noted (such as with MAT IDN, *, TRN), MAT may be used with arrays of one to eight dimensions. It is permissible to specify one array for multiple MAT parameters.

Example

MAT *array1()* = IDN

This establishes *array1* as an identity matrix, with all diagonal elements as 1 and all others as zero. This produces undefined results if *array1* is not a "square" matrix.
MAT array1() = (expr) * array2()

Each element of *array2* is multiplied by the scalar value of the *expr*, then assigned to *array1*.

MAT array1() = TRN(array2())

Transposes the row and columns from *array2* to *array1*. Arrays must be equivalent: *array1*(5,2) and *array2*(2,5). Only a square matrix may be transposed to itself.

MAT array1() = INV(array2())

Inverts the array from *array2* to *array1*. Only a square matrix may be inverted. Proof: If *array1* is then multiplied by *array2,* the resulting "*array3*" will be equal to an Identify Matrix, (MAT *array3* = *array1* * *array2* ' *array3* should now be equal to "MAT array3 IDN").

MAT a() = b() * c()

Array multiplication occurs as follows:

```
' Row Column assumption:
'    array [a]l,n = [b]l,m * [c]m,n

FOR i = 1 TO l            ' Row    [a]l = Row    [b]l
  FOR j = 1 TO n          ' Column [a]n = Column [c]n
    a(i,j) = 0#           ' # if Double-precision
    FOR k = 1 TO m        ' Column [b]m = Row    [c]m
      a(i,j) = a(i,j) + b(l,k) * c(k,j)
    NEXT
  NEXT
NEXT
```

MAX function

MAX function

Purpose Return the argument with the largest (maximum) value.

Syntax

```
y  = MAX(arg [, arg] ...)
y& = MAX&(arg& [, arg&] ...)
y$ = MAX$(arg$ [, arg$] ...)
```

Remarks These functions take any number of arguments and return the argument with the largest (maximum) value. MAX handles arguments of any

type.

MAX& handles arguments which evaluate to Long-integers (MAX& is more efficient than MAX).

MAX$ handles

arguments.

If any arguments of MAX& are outside of the range of Long-integers, the result is

undefined. Any
arguments of MAX& will be rounded to Long-integers before the comparison begins.
MAX% is recognized as a valid synonym for MAX&.

See also CHOOSE, CHOOSE&, CHOOSE$, IIF, IIF&, IIF$, MIN, MIN&, MIN$, SWITCH, SWITCH&, SWITCH$

Example
```
x% = MAX&(A, B, C, D)
x$ = MAX$("abacadabra", "cad", A$, B$(4), C$+D$+LEFT$(E$,5))
x## = MAX(1.1@@, A%/B!, C#(x)^D, E##, SIN(F&))
```

MCASE$ function

MCASE$ function

Purpose Return a mixed case version of its
argument.

Syntax `s$ = MCASE$(string_expression [,ANSI | OEM])`

Remarks MCASE$ returns a string equivalent to *string_expression*, except that the first letter of each word is capitalized, while the remaining characters are forced to lowercase. A word is considered to be a consecutive series of letters. The optional ANSI or OEM parameter specifies whether the conversion is made using the ANSI charset for the system, or the original IBM OEM charset. If no charset is specified, PowerBASIC for Windows uses the system ANSI charset, while PB/CC uses the IBM OEM charset. Only "International" characters in the range of CHR$(128) to CHR$(255) are affected by this parameter.

The OEM charset is based upon the original IBM OEM charset to ensure compatibility with programs written for all previous versions of the PowerBASIC compiler.

See also LCASE$, UCASE$

Example
```
x$ = MCASE$("Cats aren't AL.WAYS good.")
```

Result
```
Cats Aren'T Al.Ways Good.
```

ME pseudo-variable

Keyword Template

Purpose

Syntax

Remarks

See also

Example

ME pseudo-variable

Purpose A pseudo object variable to reference the current object.

Syntax `ME.Method1(param)`

Remarks ME is a pseudo-variable, which PowerBASIC automatically defines in every Method and Property. It is treated as a reference to the current object. Using ME, it's possible to call any other Method or Property which is a member of the class: *var* = ME.*Method1*(*param*)

ME can also be assigned to an appropriate object variable, or used as a Sub/Function/Method/Property parameter.

See also CLASS, INTERFACE (Direct), INTERFACE (IDBind), METHOD, PROPERTY, What is an object, anyway?

MEMORY COPY statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

MEMORY statement New!

Purpose Copy, Swap, or Fill blocks of memory.

Syntax

```
MEMORY COPY Source&, Dest&, Count&
MEMORY SWAP Source&, Dest&, Count&
MEMORY FILL Dest&, Count&, BYTE|WORD|DWORD IntegralExpr
MEMORY FILL Dest&, Count&, StrgExpr
```

Remarks The MEMORY statement may be used to copy, swap, or fill a block of memory with very high efficiency. PowerBASIC will automatically take into account the possibility that the source and destination blocks overlap and avoid corruption from that fact.

In the first form, *Count&* bytes of memory at the address specified by *Source&* is copied to the address specified by *Dest&*. In the second form, *Count&* bytes of memory at the address specified by *Source&* is exchanged with the data at the address specified by *Dest&*.

In the third form, *Count&* bytes of memory at *Dest&* are filled with one or more copies of the BYTE, WORD, or DWORD value specified by the value of *IntegralExpr*.

In the fourth form, *Count&* bytes of memory at *Dest&* are filled with one or more copies of the string *StrgExpr*.

MENU ADD POPUP statement

MENU ADD POPUP statement IMPROVED

Purpose Add a popup child menu to an existing menu.

Syntax `MENU ADD POPUP, hMenu, txt$, hPopup [AS id], state& [, AT [BYCMD] position&]`

Remarks A popup menu is a small window that "pops up" when a menu item is highlighted. This allows nesting, and gives the user an opportunity to choose from "sub-menu" items.

hMenu Handle of the parent menu which holds the popup.

txt$ Text displayed in the parent menu. An ampersand (&) may be used in the

to make the following letter into a control accelerator (hot-key). The letter appears underscored to signify that it is an accelerator.

hPopup Handle of the child popup menu to be added.

id If the option AS ID is included, *id* is a unique numeric identifier for this popup menu. *id* may be used later with a BYCMD option to reference this popup. *id* is an integral numeric value in the range of -32768 to +32767.

state& The initial state of the menu item. It can be one of the following:

%MFS_DISABLED	Disable the item so that it cannot be selected.
%MFS_ENABLED	Enable the item so that it can be selected.

position& Indicates the position in the parent menu where the popup child menu is to be inserted. If the BYCMD option is used, the popup menu is inserted prior to the menu item ID specified by *position&*. Otherwise, the popup menu is inserted at the physical *position&* within the parent menu, where *position&* = 1 for the first position, *position&* = 2 for the second, and so on. If position is not specified then the popup menu is appended to the end of the menu.

See also Dynamic Dialog Tools, ACCEL ATTACH, Menus, MENU ADD STRING, MENU ATTACH, MENU CONTEXT, MENU DELETE, MENU DRAW BAR, MENU GET STATE, MENU GET TEXT, MENU NEW BAR, MENU NEW POPUP, MENU SET STATE, MENU SET TEXT

Example See Menu Example.

MENU ADD STRING statement

MENU ADD STRING statement

Purpose Add a

or separator to an existing menu.

Syntax `MENU ADD STRING, hMenu, txt$, id&, state& [, AT [BYCMD] position&] [, CALL callback]`

Remarks A string may contain an optional command accelerator key, and also describe an equivalent keyboard accelerator combination.

hMenu Handle of the parent menu to which the string should be added.

txt$* Text to display in the parent menu. An ampersand (&) may be used in the string to make the following letter into a command accelerator (hot-key). The letter is underscored to signify that it is an accelerator. To create a horizontal separator instead of a text string, set *txt$ = "-", *id&* = 0, *state&* = 0.

Keyboard accelerators, as described in the ACCEL ATTACH statement, can be indicated in the text of a menu item, for the reference of the user. To include a keyboard accelerator description in a menu string, separate it from the menu item text with a $TAB {CHR$(9)}

	character. For example: `MENU ADD STRING, hMenu, "Cu&t" & $TAB & "CTRL+X", id&, mstate&`
id&	The unique identifier for the menu item. When a menu item is selected, *id&* is sent to the parent dialog Callback Function to notify the dialog which option was selected.
state&	The initial state of the menu item. It can be one or more of the following, combined together with the OR operator to form a bitmask:

%MFS_CHECKED	Place a checkmark next to the item.
%MFS_DEFAULT	The default menu item, displayed in bold. Only one item may be the default.
%MFS_DISABLED	Disable the menu item so that it cannot be selected.
%MFS_ENABLED	Enable the menu item so that it can be selected.
%MFS_GRAYED	Disable the menu item so that it cannot be selected, and draw it in a "grayed" state to indicate this.
%MFS_HILITE	Highlight the menu item.
%MFS_UNCHECKED	Do not place a checkmark next to the item.
%MFS_UNHILITE	Item is not highlighted.

	A state value of zero (0) provides %mfs_enabled, %mfs_unchecked, and %mfs_unhilite.
position&	Optional position in the parent menu, where the menu item should be inserted. If the BYCMD option is used, the menu item is inserted prior to the menu item ID specified by *position&*. Otherwise, the menu item is inserted at the physical *position&* within the parent menu, where *position&* = 1 for the first position, *position&* = 2 for the second, and so on. If position is not specified then the popup menu is appended to the end of the menu.
callback	Optional name of a Callback Function that will be called when the menu item is selected. This callback will be ignored when used with MENU CONTEXT as it returns the id of the selected menu item.
Restrictions	The application must call the MENU DRAW BAR statement whenever a menu changes, whether or not the menu is in a displayed dialog.
See also	Dynamic Dialog Tools, ACCEL ATTACH, Menus, MENU ADD POPUP, MENU ATTACH, MENU CONTEXT, MENU DELETE, MENU DRAW BAR, MENU GET STATE, MENU GET TEXT, MENU NEW BAR, MENU NEW POPUP, MENU SET STATE, MENU SET TEXT
Example	See Menu Example.

MENU ATTACH statement

MENU ATTACH statement

Purpose	Attach a menu to a given dialog.
Syntax	`MENU ATTACH hMenu, hDlg`
Remarks	Attaches a menu to a dialog, replacing any existing menu. The dialog is redrawn to accommodate the new menu.
hMenu	Handle of the menu to be attached.

hDlg	Handle of the dialog which holds the menu.
See also	Dynamic Dialog Tools, ACCEL ATTACH, Menus, MENU ADD POPUP, MENU ADD STRING, MENU DELETE, MENU DRAW BAR, MENU GET STATE, MENU GET TEXT, MENU NEW BAR, MENU NEW POPUP, MENU SET STATE, MENU SET TEXT
Example	See Menu Example.

MENU CONTEXT statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

MENU CONTEXT statement New!

Purpose	Create a floating context menu.
Syntax	`MENU CONTEXT hContext, x&, y&, flags& TO CmdVar`
Remarks	A context menu is a floating popup menu which is shown until the user makes a selection or dismisses it. It can appear anywhere on the screen.
hContext	Handle of a menu created with MENU NEW POPUP.
x&, y&	The parameters *x&* and *y&* specify the location of the context menu, in pixels, relative to the upper left corner of the desktop.
flags&	May be combined, as appropriate, to specify the characteristics of the context menu.

%TPM_LEFTBUTTON	Tracks the left button.
%TPM_RIGHTBUTTON	Tracks the right button.
%TPM_LEFTALIGN	Left side of the menu is aligned with *x&*.
%TPM_CENTERALIGN	Centers horizontally with *x&*.
%TPM_RIGHTALIGN	Right side of the menu is aligned with *x&*.
%TPM_TOPALIGN	Top of the menu is aligned with *y&*.
%TPM_VCENTERALIGN	Centers vertically with *y&*.
%TPM_BOTTOMALIGN	Bottom of the menu is aligned with *y&*.

CmdVar — Long integer variable where the id of the selected menu item is returned. If an optional callback is defined for a menu item with MENU ADD STRING it will be ignored when used with MENU CONTEXT.

See also — Dynamic Dialog Tools, Menus, MENU ADD STRING, MENU ADD POPUP, MENU NEW POPUP

Example

```
MENU NEW POPUP TO hPop&
MENU ADD STRING, hPop&, "one", 1, %mf_enabled
MENU ADD STRING, hPop&, "two", 2, %mf_enabled
MENU ADD STRING, hPop&, "three", 3, %mf_enabled
MENU CONTEXT hPop&, 500, 500, %tpm_leftbutton TO CommandVar&
```

MENU DELETE statement

MENU DELETE statement

Purpose — Delete a menu item from an existing menu.

Syntax — **MENU DELETE *hMenu*, [BYCMD] *position&***

Remarks — If the menu item is a popup child menu, the menu is destroyed and its memory is released.

hMenu — Handle of the menu holding the item you are deleting.

position& — Position of the item within the menu. If BYCMD is specified, *position&* refers to the unique menu identifier. Otherwise, *position&* is the position of the menu item, where *position&* = 1 for the first position, *position&* = 2 for the second, and so on.

See also — Dynamic Dialog Tools, Menus, MENU ADD POPUP, MENU ADD STRING, MENU ATTACH, MENU DRAW BAR, MENU GET STATE, MENU GET TEXT, MENU NEW BAR, MENU NEW POPUP, MENU SET STATE, MENU SET TEXT

MENU DRAW BAR statement

MENU DRAW BAR statement

Purpose — Redraw the menu bar for a given dialog.

Syntax — **MENU DRAW BAR *hDlg***

Remarks — This operation should be performed when a menu is altered dynamically after the dialog has been initially created, without regard to the visible state of the dialog.

hDlg — Handle of the dialog that owns the menu to be redrawn.

See also — Dynamic Dialog Tools, Menus, MENU ADD POPUP, MENU ADD STRING, MENU ATTACH, MENU DELETE, MENU GET STATE, MENU GET TEXT, MENU NEW BAR, MENU NEW POPUP, MENU SET STATE, MENU SET TEXT

MENU GET STATE statement

MENU GET STATE statement IMPROVED

Purpose — Return the state of a specified menu item.

Syntax — **MENU GET STATE *hMenu*, [BYCMD] *position&* TO *state&***

Remarks — Retrieves the menu flags associated with the specified menu item.

hMenu — Handle of the menu containing the item to examine.

position&	Position within the menu of the menu item to examine. If the BYCMD option is specified, *position&* specifies the unique menu item identifier of the item to examine. Otherwise, *position&* indicates the physical position of the menu item within the menu, where *position&* = 1 for the first position, *position&* = 2 for the second position, and so on.
state&	Long integer variable where the menu state will be placed. If the item does not exist, the result is -1. Otherwise the result is a bitmask containing one or more of the following, combined together with the OR operator to form the bitmask:

%MFS_CHECKED	Menu item has a checkmark next to it.
%MFS_DEFAULT	Menu item is the default item.
%MFS_DISABLED	Menu item is disabled and cannot be selected.
%MFS_ENABLED	Menu item is enabled and can be selected.
%MFS_GRAYED	Menu item is disabled and cannot be selected, and is drawn in a "grayed" state.
%MFS_HILITE	Menu item is highlighted.
%MFS_UNCHECKED	Menu item does not have a checkmark next to it.
%MFS_UNHILITE	Menu item is not highlighted.

See also Dynamic Dialog Tools, Menus, MENU ADD POPUP, MENU ADD STRING, MENU ATTACH, MENU DELETE, MENU DRAW BAR, MENU GET TEXT, MENU NEW BAR, MENU NEW POPUP, MENU SET STATE, MENU SET TEXT

MENU GET TEXT statement

MENU GET TEXT statement

Purpose	Return the text associated with a given menu item.
Syntax	**`MENU GET TEXT hMenu, [BYCMD] position& TO txt$`**
Remarks	Return the text displayed in the menu item identified by *position&*.
hMenu	Handle of the menu that contains the menu item to be examined.
position&	Position of the menu item to examine. If BYCMD is specified, *position&* refers to the unique menu item identifier of the item to examine. Otherwise, *position&* indicates the physical position of the menu item within the menu, where *position&* = 1 for the first position, *position&* = 2 for the second position, and so on.
txt$	variable where the text from the menu item will be placed.
See also	Dynamic Dialog Tools, Menus, MENU ADD POPUP, MENU ADD STRING, MENU ATTACH, MENU DELETE, MENU DRAW BAR, MENU GET STATE, MENU NEW BAR, MENU NEW POPUP, MENU SET STATE, MENU SET TEXT

MENU NEW BAR statement

MENU NEW BAR statement

Purpose	Create a new menu bar.
Syntax	**`MENU NEW BAR TO hMenu`**
Remarks	Items may be added to the menu using the MENU ADD POPUP and MENU ADD STRING statements.
hMenu	Double-word or Long-integer variable where the handle of the new menu bar will be placed.
See also	Dynamic Dialog Tools, Menus, MENU ADD POPUP, MENU ADD STRING,

MENU ATTACH, MENU DELETE, MENU DRAW BAR, MENU GET STATE, MENU GET TEXT, MENU NEW POPUP, MENU SET STATE, MENU SET TEXT

Example See Menu Example.

MENU NEW POPUP statement

MENU NEW POPUP statement

Purpose Create a new popup menu.

Syntax `MENU NEW POPUP TO hPopup`

Remarks Once created, items may be added to the popup menu using the MENU ADD POPUP and MENU ADD STRING statements.

hPopup Double-word or Long-integer variable where the handle of the new popup menu will be placed.

See also Dynamic Dialog Tools, Menus, MENU ADD POPUP, MENU ADD STRING, MENU ATTACH, MENU CONTEXT, MENU DELETE, MENU DRAW BAR, MENU GET STATE, MENU GET TEXT, MENU NEW BAR, MENU SET STATE, MENU SET TEXT

Example See Menu Example.

MENU SET STATE statement

MENU SET STATE statement IMPROVED

Purpose Set the state of a specified menu item.

Syntax `MENU SET STATE hMenu, [BYCMD] position&, state&`

Remarks Change the state of the menu item identified by *position&*.

hMenu Double-word or Long-integer variable containing the handle of the menu that contains the item to change.

position& Position within the menu, of the menu item to be changed. If the BYCMD option is specified, *position&* refers to the unique menu item identifier of the item. Otherwise, *position&* indicates the physical position of the menu item within the menu, where *position&* = 1 for the first position, *position&* = 2 for the second position, and so on.

state& The new state of the menu item. This must be one or more of the following items, combined together with the OR operator to form a bitmask:

%MFS_CHECKED	Place a checkmark next to the item.
%MFS_DEFAULT	The default menu item, displayed in bold. Only one item may be the default.
%MFS_DISABLED	Disable the menu item so that it cannot be selected.
%MFS_ENABLED	Enable the menu item so that it can be selected.
%MFS_GRAYED	Disable the menu item so that it cannot be selected, and draw it in a "grayed" state to indicate this.
%MFS_HILITE	Highlight the menu item.
%MFS_UNCHECKED	Removes any checkmark next to the item.
%MFS_UNHILITE	Removes the highlight from the item.

See also Dynamic Dialog Tools, Menus, MENU ADD POPUP, MENU ADD STRING, MENU ATTACH, MENU CONTEXT, MENU DELETE, MENU DRAW BAR,

MENU GET STATE, MENU GET TEXT, MENU NEW BAR, MENU NEW POPUP, MENU SET TEXT

MENU SET TEXT statement

MENU SET TEXT statement

Purpose Set the text of a menu item.

Syntax **MENU SET TEXT *hMenu*, [BYCMD] *position&*, *txt$***

Remarks Set the text of the menu item identified by *position&*.

hMenu Handle of the menu that contains the menu item to change.

position& Position within the menu, of the menu item to be changed. If the BYCMD option is used, *position&* specifies the unique menu item identifier of the item to change. Otherwise, *position&* indicates the physical position of the menu item within the menu, where *position&* = 1 for the first position, *position&* = 2 for the second position, and so on.

txt$ The new text for the menu item.

See also Dynamic Dialog Tools, Menus, MENU ADD POPUP, MENU ADD STRING, MENU ATTACH, MENU CONTEXT, MENU DELETE, MENU DRAW BAR, MENU GET STATE, MENU GET TEXT, MENU NEW BAR, MENU NEW POPUP, MENU SET STATE

METHOD / END METHOD statements

Keyword Template

Purpose

Syntax

Remarks

See also

Example

METHOD/END METHOD statements IMPROVED

Purpose Define a METHOD procedure within a class.

Syntax

```
[CLASS|OVERRIDE] METHOD name [<DispID>] [ALIAS "altname"] (var AS type...)
[THREADSAFE] [AS type]
  [statements]
  METHOD = expression
END METHOD
```

Remarks METHOD/END METHOD is used to define a METHOD procedure within a class. Standard methods can only be called through a virtual function table on a valid object.

A METHOD is a block of code, very similar to a user-defined function. Optionally, it can return a value, like a FUNCTION, or merely act as a subroutine, like a SUB. If the optional "AS type" is included, the method returns a value set by "*Method=expr*", or defaults to a return value of zero (0) or nul

, depending upon the type. METHOD parameters may be any variable type, including VARIANT variables. Methods may be called using any of the five following forms:

```
DIM ObjVar AS MyInterface
LET ObjVar  = NEWCOM Prgid$
1. ObjVar.Method1(param)
2. CALL ObjVar.Method1(param)
3. ObjVar.Method1(param) TO var
4. CALL ObjVar.Method1(param) TO var
5. var = ObjVar.Method1(param)
```

Forms 1 and 2 assume that the Method does not return a value, or you simply wish to discard it. Forms 3, 4, and 5 require that the Method return a value compatible with the type of variable specified as *var*. Parentheses enclosing parameters are optional in forms 1 and 3.

Methods may be declared (using AS *type*...) to return a string, any of the

types, a specific class of object variable (AS MyClass), a Variant, or a user defined Type.

> **Type Libraries only support the following data types: BYTE, WORD, DWORD, INTEGER, LONG, QUAD, SINGLE, DOUBLE, CURRENCY, OBJECT, STRING, and VARIANT. If any Methods or Properties use data types not supported by Type Libraries, you will receive a Error 581 - Type Library creation error, when using the #COM TLIB ON metastatement.**

In addition to the explicit return value which you declare, all Methods and Properties on an IAutomation or IDispatch interface have another "Hidden Return Value", which is cryptically named hResult. While the name would imply a handle for a result, it's really not a handle at all, but just a long integer value, used to indicate success or failure of the Method. After calling a Method or Property, you can retrieve the hResult value with the PowerBASIC function OBJRESULT. The most significant bit of the value is known as the severity bit. That bit is 0 (value is positive) for success, or 1 (value is negative) for failure. The remaining bits are used to convey error codes and additional status information. If you call any object Method/Property (either Dispatch or Direct), and the severity bit of hResult is set, PowerBASIC generates Run-Time error 99: Object error. When you create a Method or Property, PowerBASIC automatically returns an hResult of zero, which implies success. You can return a non-zero hResult value by executing a METHOD OBJRESULT = *expr* within a Method, or PROPERTY OBJRESULT = *expr* within a Property.

Class Methods

A CLASS METHOD is one which is private to the class in which it is located. That is, it may only be called from a METHOD or PROPERTY in the same class. The CLASS METHOD must be located within a CLASS block, but outside of any INTERFACE blocks. This shows it is a direct member of the class, rather than a member of an interface.

```
CLASS MyClass
  INSTANCE MyVar AS LONG

  CLASS METHOD MyClassMethod(BYVAL param AS LONG) AS STRING
    METHOD = "My" + STR$(param + MyVar)
  END METHOD

  INTERFACE MyInterface
    INHERIT IUNKNOWN
    METHOD MyMethod()
      Result$ = ME.MyClassMethod(66)
    END METHOD
  END INTERFACE
END CLASS
```

In the above example, MyClassMethod() is a CLASS METHOD, and is always accessed using the pseudo-object ME (in this case ME.MyClassMethod). Class methods are never accessible from outside a class, nor are they ever described or published in a type library.

By definition, there is no reason to have a private PROPERTY, so PowerBASIC does not offer a CLASS PROPERTY structure.

Constructors and Destructors

There are two special class methods which you may optionally add to a class. They meet a very specific need: automatic initialization when an object is created, and cleanup when an object is destroyed. Technically, they are known as constructor and destructor methods, and can perform almost any functionality needed by your object: initialization of variables, reading/writing data to/from disk, etc. You do not call these methods directly from your code. If they are present in your class, PowerBASIC automatically calls them each time an object of that class is created or destroyed. If you choose to use them, these special class methods must be named CREATE and DESTROY. They may take no parameters, and may not return a result. They are defined at the class level, so they may never appear within an INTERFACE definition.

```
CLASS MyClass
  INSTANCE MyVar AS LONG

  CLASS METHOD CREATE()
    ' Do initialization
  END METHOD

  CLASS METHOD Destroy()
    ' Do cleanup
  END METHOD

  INTERFACE MyInterface
    INHERIT IUNKNOWN
    METHOD MyMethod()
      ' Do things
    END METHOD
  END INTERFACE
END CLASS
```

As displayed above, CREATE and DESTROY must be placed at the class level, but outside of any interface block. You should note that it's not possible to name any standard method (one that's accessible through an interface) as CREATE or DESTROY. That's just to help you remember the rules for a constructor or destructor. However, you may use these names as needed to describe a method external to your program.

A very important caution: You must never create an object of the current class in a CREATE method. To do so will cause CREATE to be executed again and again until all available memory is consumed. This is a fatal error, from which recovery is impossible.

Override Methods

You can add to, or replace, the functionality of a particular method or property of an inherited base class by coding a replacement which is preceded by the word OVERRIDE. The overriding method must have the same name and signature (parameters, return value, etc.) as the one it replaces.

Dispatch ID

Every method and property in a dual interface needs a positive, long integer value to identify it. That integer value is known as a DispID (Dispatch ID), and it's used internally by COM services to call the correct function on a Dispatch interface. You can optionally specify a particular DispID by enclosing it in angle brackets immediately following the Method/Property name:

```
METHOD  MethodOne <76> ()
```

If you don't specify a DispID, PowerBASIC will assign a random value for you. This is fine for internal objects, but may cause a failure for published COM objects, as the DispID could change each time you compile your program. It is particularly important that you specify a DispID for each Method/Property in a COM Event Interface.

BYREF and BYVAL attributes

Just like a SUB or FUNCTION, PowerBASIC uses

parameters as the default form, unless you specify a override. Either key word can be placed before the parameter name, along with IN, OUT, and INOUT, as described later.

BYVAL	A copy of the data value is placed on the stack as a parameter. The copy is destroyed when the METHOD ends. BYVAL parameters default to an IN parameter, if no explicit direction is specified.
BYREF	A pointer to the data is placed on the stack as a parameter. If the data is a variable, any changes to the parameter are passed back to the caller in the variable. If the data is an expression, it is destroyed when the METHOD ends. BYREF parameters default to an INOUT parameter, if no explicit direction is specified.

Direction attributes

METHOD parameters may also specify the direction in which data is passed between the caller and callee:

IN	Data is passed from the caller to the METHOD. Generally speaking, you'll find that almost all IN parameters are passed BYVAL, and that is highly recommended. However, it is possible to pass them BYREF if necessary.
OUT	Data is passed from the METHOD back to the caller. All OUT parameters must be passed BYREF.
INOUT	Data is passed from the caller to the METHOD, and results are returned to the caller in the same parameter. All INOUT parameters must be passed BYREF.

In many cases, the direction of a parameter can be inferred directly from the BYVAL/BYREF attribute (BYVAL=IN, BYREF=OUT). However, we recommend that you include the direction attribute as an added means of self-documentation. Each METHOD parameter name may be preceded by one of BYVAL/BYREF, and one of IN/OUT/INOUT, in any sequence.

You should note an interesting rule of COM objects: **IN parameters are read-only. They may not be altered.**

IN parameters are considered by COM rules to be "constant" which may not be altered, because they are values which are not returned to the caller. However, since this is not a rule normally applied to a standard SUB or FUNCTION, it can allow programming bugs which are most difficult to find and correct. For this reason, PowerBASIC automatically protects you from this issue with no action needed on your part. When writing METHOD or PROPERTY code in PowerBASIC, you may freely assign new values to BYVAL/IN parameters. They will simply be discarded when the METHOD exits. Of course, not every programming language protects you in this way, so you must use caution if you create a COM METHOD in another compiler.

Using OPTIONAL/OPT

METHOD statements may specify one or more parameters as optional by preceding the parameter with either the keyword

(or the abbreviation OPT). When a parameter is declared optional, all subsequent parameters in the declaration are optional as well, whether or not they specify an explicit OPTIONAL or OPT directive.

VARIANT variables are particularly well suited for use as an optional parameter. If the calling code omits an optional VARIANT parameter, (BYVAL or BYREF), PowerBASIC (and most other compilers) substitute a variant of type %VT_ERROR which contains an error value of %DISP_E_PARAMNOTFOUND (&H80020004). In this case, you can check for this value directly, or use the ISMISSING function to determine whether the parameter was physically passed or not.

When optional parameters (other than VARIANT) are omitted from the calling code, the stack area normally reserved for those parameters is zero-filled.

If the parameter is defined as a BYVAL parameter, it will have the value zero. For TYPE or UNION variables passed BYVAL, the compiler will pass a string of binary zeroes of length SIZEOF(*Type_or_union_var*).

If the parameter is defined as a BYREF parameter, VARPTR(*Varname*) will equal zero; when this is true, any attempt to use *Varname* in your code will result in a General Protection Fault or memory corruption. You should use the ISMISSING() function first to determine whether it is safe to access the parameter.

THREADSAFE Option Descriptor

If you include the option THREADSAFE, PowerBASIC automatically establishes a semaphore which allows only one

to execute it at a time. Others must wait until the first thread exits the THREADSAFE procedure before they are allowed to begin.

METRICS function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

METRICS function New!

Purpose Retrieves information or dimensions of system elements.

Syntax `MetricVar = METRICS(MetricName)`

Remarks Returns information about the particular system metric specified by the parameter *MetricName*. All dimensions are specified in pixels. For example:

```
MetricVar& = METRICS(Scroll.Horz)
```

The above example retrieves the height (in pixels) of a horizontal scrollbar, and assigns it to the variable *MetricVar&*.

MetricName

MetricName	**Description**
BORDER.X	The width of a window border.
BORDER.Y	The height of a window border.
CAPTION	The height of a normal caption area.
EDGE.X	The width of a 3-D border.
EDGE.Y	The height of a 3-D border.
FRAME.FIXED.X	The thickness of the horizontal frame of a window which is fixed

	size (one which cannot be resized).
FRAME.FIXED.Y	The thickness of the vertical frame of a window which is fixed size (one which cannot be resized).
FRAME.RESIZE.X	The thickness of the horizontal frame of a window which can be resized.
FRAME.RESIZE.Y	The thickness of the vertical frame of a window which can be resized.
ICON.X	The default width of an icon.
ICON.Y	The default height of an icon.
ICONSPACE.X	The width of a grid cell for items in large icon view.
ICONSPACE.Y	The height of a grid cell for items in large icon view.
MAXIMIZED.X	The width of a maximized top-level window.
MAXIMIZED.Y	The height of a maximized top-level window.
MENUBAR	The height of a single-line menu bar.
MINIMUM.X	The minimum width of a window.
MINIMUM.Y	The minimum height of a window.
SCROLL.HORZ	The height of a horizontal scrollbar.
SCROLL.VERT	The width of a vertical scrollbar.

MID$ function

MID$ function IMPROVED

Purpose Returns a part of a

.

Syntax

```
s$ = MID$(StringExpr, Start& [, Count&])
s$ = MID$(StringExpr, Start& TO End&)
```

Remarks The MID$ function returns a part of a string expression. The first form tells the number of characters to extract, while the second form tells the start and end position instead. Both forms provide the same functionality, so the choice is just a matter of programmer convenience.

Start& and *End&* are positions in the string, starting with 1 as the first character. *Count&* tells the number of characters to extract. For example, both of the following examples return "wer".

```
a$ = MID$("PowerBASIC", 3, 3)
a$ = MID$("PowerBASIC", 3 TO 5)
```

If *Count&* is omitted, or there aren't enough characters in *StringExpr*, all remaining characters are returned. If there are no characters at the *Start&* position, an empty string is returned.

If *Start&* or *End&* are negative, the positions are counted backwards from the end of the string (-1 is the last character). If *Count&* is negative, it is interpreted as LEN(*string_expression*)-ABS(*Count&*).

See also EXTRACT$, INSTR, LEFT$, LTRIM$, MID$ statement, RIGHT$, RTRIM$, SPLIT, TALLY, TRIM$, VERIFY

Example

```
a$ = MID$("PowerBASIC", 4, 2)    ' returns "er"
a$ = MID$("PowerBASIC", 4)       ' returns "erBASIC"
a$ = MID$("PowerBASIC", 20)      ' returns a null string
a$ = MID$("1234567890",3,-4)     ' returns "345678"
a$ = MID$("abcde", -3, 2)        ' returns "cd"
a$ = MID$("PowerBASIC", 4 TO 6)  ' returns "erB"
a$ = MID$("PowerBASIC", 4 TO 99) ' returns "erBASIC"
```

MID$ statement

MID$ statement IMPROVED

Purpose Replace characters in a variable.

Syntax

```
MID$(StringVar, Start& [, Count&]) = replacement
MID$(StringVar, Start& TO End&      = replacement
```

Remarks The MID$ statement replaces characters in a string variable. The first form tells the number of characters to replace, while the second form tells the start and end position instead. Both forms provide the same functionality, so the choice is just a matter of programmer convenience.

Start& and *End&* are positions in the string, starting with 1 as the first character. *Count&* tells the number of characters to replace.

If *Count&* is omitted, or there aren't enough characters in *StringVar*, all remaining characters are replaced. If there are no characters at the *Start&* position, no operation is performed.

If *Start&* or *End&* are negative, the positions are counted backwards from the end of the string (-1 is the last character). If *Count&* is negative, it is interpreted as LEN(*string_expression*)-ABS(*Count&*).

The replacement will never extend past the end of *StringVar*. In other words, MID$ cannot alter the length of a string.

Restrictions If *Start&* evaluates to a position outside of the string on either side, or if *Start&* is zero, no operation is performed.

See also BUILD$, INSTR, LTRIM$, MID$ function, REMOVE$, REPLACE, RTRIM$, TALLY, TRIM$, VERIFY

Example

```
DummyString$ = "1234567890"
FOR M = 1 TO 10
  TestString$ = DummyString$
  MID$(TestString$,1,M) = "PowerBASIC"
NEXT M
```

Result

```
P234567890
Po34567890
Pow4567890
Powe567890
 ...
PowerBAS90
PowerBASI0
PowerBASIC
```

MIN function

MIN function

Purpose Return the argument with the smallest (minimum) value.

Syntax

```
y  = MIN(arg, arg [, arg] ...)
y& = MIN&(arg&, arg& [, arg&] ...)
y$ = MIN$(arg$, arg$ [, arg$] ...)
```

Remarks These functions take any number of arguments and return the argument with the smallest (minimum) value. MIN handles arguments of any type.

MIN& handles arguments that evaluate to Integers and Long-integers (MIN& is more efficient than MIN).

MIN$ handles

arguments.

If any arguments of MIN& are outside of the range of Long-integers, the result is undefined. Any

arguments of MIN& will be rounded to Long-integers before the comparison begins.

MIN% is recognized as a valid synonym for MIN&.

See also CHOOSE, CHOOSE&, CHOOSE$, IIF, IIF&, IIF$, MAX, MAX&, MAX$, SWITCH, SWITCH&, SWITCH$

Example

```
x& = MIN&(A, B, C, D)
x$ = MIN$("abacadabra","cad", A$, B$(4), C$ + D$ + LEFT$(E$,5))
x## = MIN(1.1@@, A%/B!, C#(x)^D, E##, SIN(F&))
```

MKBYT$ function

MKBYT$, MKCUR$, MKCUX$, MKD$, MKDWD$, MKE$, MKI$, MKL$, MKQ$, MKS$ and MKWRD$ functions

Purpose Converts a

value into an ANSI .

Syntax

```
AnsiStringVar$ = MKBYT$(byte_expr)
AnsiStringVar$ = MKCUR$(currency_expr)
AnsiStringVar$ = MKCUX$(extended_currency_expr)
AnsiStringVar$ = MKD$(double_precision_expr)
AnsiStringVar$ = MKDWD$(double_word_expr)
AnsiStringVar$ = MKE$(extended_precision_expr)
AnsiStringVar$ = MKI$(integer_expr)
AnsiStringVar$ = MKL$(long_integer_expr)
AnsiStringVar$ = MKQ$(quad_integer_expr)
AnsiStringVar$ = MKS$(single_precision_expr)
AnsiStringVar$ = MKWRD$(word_expr)
```

Remarks The MKx functions return the binary representations of a number as a set of bytes in an ANSI string. Do not confuse these functions with the STR$ or FORMAT$ functions, which return a printable string.

In all but the most extreme cases, the returned string should only be stored as an ANSI string or UDT which consist of single bytes. WIDE (Unicode) strings consist of a series of 2-byte words which will generally yield undefined results.

The CV*x* functions are complementary to the MK*x* functions. They convert the binary representation in a string to an actual numeric value:

Function	Converts to	From
MKBYT$	1-byte string	Byte
MKCUR$	8-byte string	Currency
MKCUX$	8-byte string	Extended-currency
MKD$	8-byte string	Double-precision
MKDWD$	4-byte string	Double-word
MKE$	10-byte string	Extended-precision
MKI$	2-byte string	Integer

MKL$	4-byte string	Long-integer
MKQ$	8-byte string	Quad-integer
MKS$	4-byte string	Single-precision
MKWRD$	2-byte string	Word

See also CVI and associated functions

MKCUR$ function

MKBYT$, MKCUR$, MKCUX$, MKD$, MKDWD$, MKE$, MKI$, MKL$, MKQ$, MKS$ and MKWRD$ functions

Purpose Converts a value into an ANSI .

Syntax

```
AnsiStringVar$ = MKBYT$(byte_expr)
AnsiStringVar$ = MKCUR$(currency_expr)
AnsiStringVar$ = MKCUX$(extended_currency_expr)
AnsiStringVar$ = MKD$(double_precision_expr)
AnsiStringVar$ = MKDWD$(double_word_expr)
AnsiStringVar$ = MKE$(extended_precision_expr)
AnsiStringVar$ = MKI$(integer_expr)
AnsiStringVar$ = MKL$(long_integer_expr)
AnsiStringVar$ = MKQ$(quad_integer_expr)
AnsiStringVar$ = MKS$(single_precision_expr)
AnsiStringVar$ = MKWRD$(word_expr)
```

Remarks The MKx functions return the binary representations of a number as a set of bytes in an ANSI string. Do not confuse these functions with the STR$ or FORMAT$ functions, which return a printable string.

In all but the most extreme cases, the returned string should only be stored as an ANSI string or UDT which consist of single bytes. WIDE (Unicode) strings consist of a series of 2-byte words which will generally yield undefined results.

The CV*x* functions are complementary to the MK*x* functions. They convert the binary representation in a string to an actual numeric value:

Function	Converts to	From
MKBYT$	1-byte string	Byte
MKCUR$	8-byte string	Currency
MKCUX$	8-byte string	Extended-currency
MKD$	8-byte string	Double-precision
MKDWD$	4-byte string	Double-word
MKE$	10-byte string	Extended-precision
MKI$	2-byte string	Integer
MKL$	4-byte string	Long-integer
MKQ$	8-byte string	Quad-integer
MKS$	4-byte string	Single-precision
MKWRD$	2-byte string	Word

See also CVI and associated functions

MKCUX$ function

MKBYT$, MKCUR$, MKCUX$, MKD$, MKDWD$, MKE$, MKI$, MKL$, MKQ$, MKS$ and MKWRD$ functions

Purpose Converts a

value into an ANSI .

Syntax

```
AnsiStringVar$ = MKBYT$(byte_expr)
AnsiStringVar$ = MKCUR$(currency_expr)
AnsiStringVar$ = MKCUX$(extended_currency_expr)
AnsiStringVar$ = MKD$(double_precision_expr)
AnsiStringVar$ = MKDWD$(double_word_expr)
AnsiStringVar$ = MKE$(extended_precision_expr)
AnsiStringVar$ = MKI$(integer_expr)
AnsiStringVar$ = MKL$(long_integer_expr)
AnsiStringVar$ = MKQ$(quad_integer_expr)
AnsiStringVar$ = MKS$(single_precision_expr)
AnsiStringVar$ = MKWRD$(word_expr)
```

Remarks The MKx functions return the binary representations of a number as a set of bytes in an ANSI string. Do not confuse these functions with the STR$ or FORMAT$ functions, which return a printable string.

In all but the most extreme cases, the returned string should only be stored as an ANSI string or UDT which consist of single bytes. WIDE (Unicode) strings consist of a series of 2-byte words which will generally yield undefined results.

The CV*x* functions are complementary to the MK*x* functions. They convert the binary representation in a string to an actual numeric value:

Function	Converts to	From
MKBYT$	1-byte string	Byte
MKCUR$	8-byte string	Currency
MKCUX$	8-byte string	Extended-currency
MKD$	8-byte string	Double-precision
MKDWD$	4-byte string	Double-word
MKE$	10-byte string	Extended-precision
MKI$	2-byte string	Integer
MKL$	4-byte string	Long-integer
MKQ$	8-byte string	Quad-integer
MKS$	4-byte string	Single-precision
MKWRD$	2-byte string	Word

See also CVI and associated functions

MKD$ function

MKBYT$, MKCUR$, MKCUX$, MKD$, MKDWD$, MKE$, MKI$, MKL$, MKQ$, MKS$ and MKWRD$ functions

Purpose Converts a

value into an ANSI .

Syntax

```
AnsiStringVar$ = MKBYT$(byte_expr)
AnsiStringVar$ = MKCUR$(currency_expr)
AnsiStringVar$ = MKCUX$(extended_currency_expr)
AnsiStringVar$ = MKD$(double_precision_expr)
AnsiStringVar$ = MKDWD$(double_word_expr)
AnsiStringVar$ = MKE$(extended_precision_expr)
AnsiStringVar$ = MKI$(integer_expr)
AnsiStringVar$ = MKL$(long_integer_expr)
AnsiStringVar$ = MKQ$(quad_integer_expr)
AnsiStringVar$ = MKS$(single_precision_expr)
AnsiStringVar$ = MKWRD$(word_expr)
```

Remarks

The MKx functions return the binary representations of a number as a set of bytes in an ANSI string. Do not confuse these functions with the STR$ or FORMAT$ functions, which return a printable string.

In all but the most extreme cases, the returned string should only be stored as an ANSI string or UDT which consist of single bytes. WIDE (Unicode) strings consist of a series of 2-byte words which will generally yield undefined results.

The CV*x* functions are complementary to the MK*x* functions. They convert the binary representation in a string to an actual numeric value:

Function	Converts to	From
MKBYT$	1-byte string	Byte
MKCUR$	8-byte string	Currency
MKCUX$	8-byte string	Extended-currency
MKD$	8-byte string	Double-precision
MKDWD$	4-byte string	Double-word
MKE$	10-byte string	Extended-precision
MKI$	2-byte string	Integer
MKL$	4-byte string	Long-integer
MKQ$	8-byte string	Quad-integer
MKS$	4-byte string	Single-precision
MKWRD$	2-byte string	Word

See also CVI and associated functions

MKDIR statement

MKDIR statement

Purpose Create a subdirectory/folder (like the DOS MKDIR command).

Syntax **MKDIR** ***path$***

Remarks

path$ is a string expression describing the directory to be created.

MKDIR (make directory) creates the subdirectory specified by *path$*. If you try to create a directory that already exists, a run-time Error 75 occurs ("Path/file access error"). If *path$* includes an parent folder that does not exist, a run-time Error 76 occurs ("Path not found").

MKDIR can use Long File Names (LFNs).

See also CHDIR, RMDIR

Example

```
MKDIR "C:\Program Files\Company\Application Data"
```

MKDWD$ function

MKBYT$, MKCUR$, MKCUX$, MKD$, MKDWD$, MKE$, MKI$, MKL$, MKQ$, MKS$ and MKWRD$ functions

Purpose Converts a

value into an ANSI .

Syntax

```
AnsiStringVar$ = MKBYT$(byte_expr)
AnsiStringVar$ = MKCUR$(currency_expr)
AnsiStringVar$ = MKCUX$(extended_currency_expr)
AnsiStringVar$ = MKD$(double_precision_expr)
AnsiStringVar$ = MKDWD$(double_word_expr)
AnsiStringVar$ = MKE$(extended_precision_expr)
AnsiStringVar$ = MKI$(integer_expr)
AnsiStringVar$ = MKL$(long_integer_expr)
AnsiStringVar$ = MKQ$(quad_integer_expr)
AnsiStringVar$ = MKS$(single_precision_expr)
AnsiStringVar$ = MKWRD$(word_expr)
```

Remarks The MKx functions return the binary representations of a number as a set of bytes in an ANSI string. Do not confuse these functions with the STR$ or FORMAT$ functions, which return a printable string.

In all but the most extreme cases, the returned string should only be stored as an ANSI string or UDT which consist of single bytes. WIDE (Unicode) strings consist of a series of 2-byte words which will generally yield undefined results.

The CV*x* functions are complementary to the MK*x* functions. They convert the binary representation in a string to an actual numeric value:

Function	Converts to	From
MKBYT$	1-byte string	Byte
MKCUR$	8-byte string	Currency
MKCUX$	8-byte string	Extended-currency
MKD$	8-byte string	Double-precision
MKDWD$	4-byte string	Double-word
MKE$	10-byte string	Extended-precision
MKI$	2-byte string	Integer
MKL$	4-byte string	Long-integer
MKQ$	8-byte string	Quad-integer
MKS$	4-byte string	Single-precision
MKWRD$	2-byte string	Word

See also CVI and associated functions

MKE$ function

MKBYT$, MKCUR$, MKCUX$, MKD$, MKDWD$, MKE$, MKI$, MKL$, MKQ$, MKS$ and MKWRD$ functions

Purpose Converts a

value into an ANSI .

Syntax

```
AnsiStringVar$ = MKBYT$(byte_expr)
AnsiStringVar$ = MKCUR$(currency_expr)
AnsiStringVar$ = MKCUX$(extended_currency_expr)
AnsiStringVar$ = MKD$(double_precision_expr)
AnsiStringVar$ = MKDWD$(double_word_expr)
AnsiStringVar$ = MKE$(extended_precision_expr)
AnsiStringVar$ = MKI$(integer_expr)
AnsiStringVar$ = MKL$(long_integer_expr)
AnsiStringVar$ = MKQ$(quad_integer_expr)
AnsiStringVar$ = MKS$(single_precision_expr)
AnsiStringVar$ = MKWRD$(word_expr)
```

Remarks

The MKx functions return the binary representations of a number as a set of bytes in an ANSI string. Do not confuse these functions with the STR$ or FORMAT$ functions, which return a printable string.

In all but the most extreme cases, the returned string should only be stored as an ANSI string or UDT which consist of single bytes. WIDE (Unicode) strings consist of a series of 2-byte words which will generally yield undefined results.

```

```
AnsiStringVar$ = MKS$(single_precision_expr)
AnsiStringVar$ = MKWRD$(word_expr)
```

Remarks

The MKx functions return the binary representations of a number as a set of bytes in an ANSI string. Do not confuse these functions with the STR$ or FORMAT$ functions, which return a printable string.

In all but the most extreme cases, the returned string should only be stored as an ANSI string or UDT which consist of single bytes. WIDE (Unicode) strings consist of a series of 2-byte words which will generally yield undefined results.

The CV*x* functions are complementary to the MK*x* functions. They convert the binary representation in a string to an actual numeric value:

Function	Converts to	From
MKBYT$	1-byte string	Byte
MKCUR$	8-byte string	Currency
MKCUX$	8-byte string	Extended-currency
MKD$	8-byte string	Double-precision
MKDWD$	4-byte string	Double-word
MKE$	10-byte string	Extended-precision
MKI$	2-byte string	Integer
MKL$	4-byte string	Long-integer
MKQ$	8-byte string	Quad-integer
MKS$	4-byte string	Single-precision
MKWRD$	2-byte string	Word

MKQ$	8-byte string	Quad-integer
MKS$	4-byte string	Single-precision
MKWRD$	2-byte string	Word

See also CVI and associated functions

MKS$ function

MKBYT$, MKCUR$, MKCUX$, MKD$, MKDWD$, MKE$, MKI$, MKL$, MKQ$, MKS$ and MKWRD$ functions

Purpose Converts a
value into an ANSI .

Syntax

```
AnsiStringVar$ = MKBYT$(byte_expr)
AnsiStringVar$ = MKCUR$(currency_expr)
AnsiStringVar$ = MKCUX$(extended_currency_expr)
AnsiStringVar$ = MKD$(double_precision_expr)
AnsiStringVar$ = MKDWD$(double_word_expr)
AnsiStringVar$ = MKE$(extended_precision_expr)
AnsiStringVar$ = MKI$(integer_expr)
AnsiStringVar$ = MKL$(long_integer_expr)
AnsiStringVar$ = MKQ$(quad_integer_expr)
AnsiStringVar$ = MKS$(single_precision_expr)
AnsiStringVar$ = MKWRD$(word_expr)
```

Remarks The MKx functions return the binary representations of a number as a set of bytes in an ANSI string. Do not confuse these functions with the STR$ or FORMAT$ functions, which return a printable string.

In all but the most extreme cases, the returned string should only be stored as an ANSI string or UDT which consist of single bytes. WIDE (Unicode) strings consist of a series of 2-byte words which will generally yield undefined results.

The CV*x* functions are complementary to the MK*x* functions. They convert the binary representation in a string to an actual numeric value:

Function	Converts to	From
MKBYT$	1-byte string	Byte
MKCUR$	8-byte string	Currency
MKCUX$	8-byte string	Extended-currency
MKD$	8-byte string	Double-precision
MKDWD$	4-byte string	Double-word
MKE$	10-byte string	Extended-precision
MKI$	2-byte string	Integer
MKL$	4-byte string	Long-integer
MKQ$	8-byte string	Quad-integer
MKS$	4-byte string	Single-precision
MKWRD$	2-byte string	Word

See also CVI and associated functions

MKWRD$ function

MKBYT$, MKCUR$, MKCUX$, MKD$, MKDWD$, MKE$, MKI$, MKL$, MKQ$, MKS$ and MKWRD$ functions

Purpose Converts a

value into an ANSI .

Syntax

```
AnsiStringVar$ = MKBYT$(byte_expr)
AnsiStringVar$ = MKCUR$(currency_expr)
AnsiStringVar$ = MKCUX$(extended_currency_expr)
AnsiStringVar$ = MKD$(double_precision_expr)
AnsiStringVar$ = MKDWD$(double_word_expr)
AnsiStringVar$ = MKE$(extended_precision_expr)
AnsiStringVar$ = MKI$(integer_expr)
AnsiStringVar$ = MKL$(long_integer_expr)
AnsiStringVar$ = MKQ$(quad_integer_expr)
AnsiStringVar$ = MKS$(single_precision_expr)
AnsiStringVar$ = MKWRD$(word_expr)
```

Remarks The MKx functions return the binary representations of a number as a set of bytes in an ANSI string. Do not confuse these functions with the STR$ or FORMAT$ functions, which return a printable string.

In all but the most extreme cases, the returned string should only be stored as an ANSI string or UDT which consist of single bytes. WIDE (Unicode) strings consist of a series of 2-byte words which will generally yield undefined results.

The CV*x* functions are complementary to the MK*x* functions. They convert the binary representation in a string to an actual numeric value:

MKL$	4-byte string	Long-integer
MKQ$	8-byte string	Quad-integer
MKS$	4-byte string	Single-precision
MKWRD$	2-byte string	Word

See also CVI and associated functions

MOD operator

MOD operator

Purpose Return the remainder of the division between two numbers.

Syntax ***p MOD q***

Remarks The MOD operator divides the two operands, *p* and *q*, and returns the remainder of that division. The result of the initial division is truncated to an

value, before the remainder is calculated. See the example below.
The remainder may be a
value. MOD is often considered to complement integral division.

See Also [LET]

Example

```
lResult1& = 10& MOD 3&   ' Returns 1&
fResult2! = 13! MOD 2.7! ' Returns 2.2!

iStack&   = 1023&
HiStack& = iStack& \ 256&  ' Returns 3&
LoStack& = iStack& MOD 256 ' Returns 255&

' c! and d! are calculated equivalently
a! = 13
b! = 2.7
c! = a! MOD b!
d! = a! - FIX(a! / b!) * b!

CurrentLine = 1
WHILE CurrentLine < Lines
  PrintLine txt$(CurrentLine)
  IF (CurrentLine MOD 55) = 0 THEN DoFormFeed
  INCR CurrentLine
WEND
```

MONTHNAME$ function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

MONTHNAME$ function New!

Purpose Converts a Month number to the associated name.

Syntax `s$ = MONTHNAME$(MonthNumber&)`

Remarks The MONTHNAME$ function converts a Month number into a
representing its associated name. The argument must be in the range of 1 through 12, representing the names January, February, etc.

See also [DATE$], [DAYNAME$], [POWERTIME]

MOUSEPTR statement

MOUSEPTR statement

Purpose Change the mouse pointer (cursor) to a new shape.

Syntax `MOUSEPTR style [TO var&]`

Remarks If the optional TO clause is included, the handle of the previous cursor is assigned to *var&*. If the operation fails, the value zero is assigned to *var&*. Normally, the Long integer or DWORD value style should be in the range of 1 through 13 to choose one of the stock cursor shapes as follows:

style&	**Definition**
0	Hide mouse pointer **
1	Arrow
2	Cross
3	I-Beam
4	Arrow
5	Sizing pointer (all directions)
6	Sizing pointer (NE-SW diagonal)
7	Sizing pointer (vertical)
8	Sizing pointer (NW-SE diagonal)
9	Sizing pointer (horizontal)
10	Up arrow
11	Hourglass ("Busy" or "Wait" pointer)
12	No mouse pointer
13	App Starting (arrow with an hourglass)

** If *style&* = 0 then the OS may restore the cursor if it is moved.

If style is outside the range 0 through 13, it must contain a valid handle to a cursor, such as the value which was returned by a prior invocation of MOUSEPTR. This allows the programmer to restore a previous cursor style.

The mouse pointer is only changed for dialogs and windows in your application. If the mouse pointer is moved over another application or the desktop, the pointer will change to the default for that application/process. In GUI applications, MOUSEPTR can be useful in %WM_SETCURSOR message handler routines that override the default cursor handling.

MSGBOX function

MSGBOX function

Purpose Display a message box containing a text

and an optional title, using one or more styles, and returning the button selected by the user.

Syntax ***lResult&* = MSGBOX(*txt$* [, [*style&*], *title$*])**

Remarks The MSGBOX function is comprised of the following elements:

txt$ Indicates the text to display within the message box.

style& Optional parameter which determines the appearance of the message box. Some styles may be combined (OR'ed together) to specify the button and icon displayed in the message box. If style& is omitted, PowerBASIC substitutes %MB_OK. The following styles are defined in WIN32API.INC, in the form of numeric equates:

%MB_OK	Display OK button (default)
%MB_OKCANCEL	Display OK and Cancel buttons
%MB_ABORTRETRYIGNORE	Display Abort, Retry and Ignore
%MB_YESNOCANCEL	Display Yes, No and Cancel
%MB_YESNO	Display Yes and No buttons
%MB_RETRYCANCEL	Display Retry and Cancel buttons

%MB_ICONERROR	Display Error icon (stop sign)
%MB_ICONINFORMATION	Display Information icon ("i")
%MB_ICONQUESTION	Display Query icon (question mark)
%MB_ICONWARNING	Display Warning icon (exclamation)
%MB_DEFBUTTON1	Default to 1st button (default)
%MB_DEFBUTTON2	Default to 2nd button
%MB_DEFBUTTON3	Default to 3rd button
%MB_APPLMODAL	Application Modal - Despite the name, the user can continue to interact with other dialogs without dismissing the MSGBOX. (default)
%MB_SYSTEMMODAL	System Modal - Operates identically to % MB_APPLMODAL, except the MSGBOX is given the %WS_EX_TOPMOST style so that it remains above all other windows and dialogs.
%MB_TASKMODAL	Task Modal - All top-level windows belonging to the current application are disabled until the MSGBOX is dismissed. %MB_TASKMODAL is commonly used to display a truly modal MSGBOX.

title$* Optional title to be displayed in the caption of the message box. If *title$ is not specified, "PowerBASIC" is used automatically.

lResult& Identifies the Button selected by the user. This will be equal to one of the following equates:

%IDOK	OK button
%IDCANCEL	Cancel button
%IDABORT	Abort button
%IDRETRY	Retry button
%IDIGNORE	Ignore button
%IDYES	Yes button
%IDNO	No button

Additional styles may be found in WIN32API.INC in the section prefixed with %MB_. If you are not interested in which button the user selects, use a MSGBOX statement rather than a MSGBOX function.

A question mark may be used as an abbreviation for the MSGBOX statement.

Restrictions Strings displayed by the MSGBOX function are displayed only up to the first $NUL character, if any.

See also INPUTBOX$, MSGBOX statement, TXT pseudo-object

Example

```
lResult& = MSGBOX("Overwrite registry file?", %MB_OKCANCEL OR %
MB_DEFBUTTON2 _
             OR %MB_TASKMODAL, "Critical Warning")
```

MSGBOX statement

MSGBOX statement

Purpose Display a message box containing a text
 and optional title, using one or more styles.

Syntax

```
MSGBOX txt$ [, [style%], title$]
? txt$ [, [style%], title$]
```

Remarks The MSGBOX statement comprises the following elements:

txt$ Text to display within the message box.

style& Optional parameter which determines the appearance of the message box. Some styles may be combined (OR'ed together) to specify the button and icon displayed in the message box. If *style&* is omitted, PowerBASIC substitutes %MB_OK. The following are some of the more common styles used with the MSGBOX statement (also see the MSGBOX function for more information):

%MB_OK	Display OK button (default)
%MB_ICONERROR	Display Error icon (stop sign)
%MB_ICONINFORMATION	Display Information icon ("i")
%MB_ICONWARNING	Display Warning icon (exclamation)
%MB_APPLMODAL	Application Modal - Despite the name, the user can continue to interact with other dialogs without dismissing the MSGBOX. (default)
%MB_SYSTEMMODAL	System Modal - Operates identically to % MB_APPLMODAL, except the MSGBOX is given the %WS_EX_TOPMOST style so that it remains above all other windows and dialogs.
%MB_TASKMODAL	Task Modal - All top-level windows belonging to the current application are disabled until the MSGBOX is dismissed. %MB_TASKMODAL is commonly used to display a truly modal MSGBOX.

Additional styles may be found in WIN32API.INC, in the section prefixed with %MB_. If you are interested in which button the user selects, use a MSGBOX function rather than a MSGBOX statement.

title$* Determines the title to be displayed in the caption of the message box. If *title$ is not specified, "PowerBASIC" is used automatically.

The MSGBOX statement may be represented by the query (?) character as a shortcut. This is similar to the behavior in the PowerBASIC Console Compiler (PB/CC), where the query character is recognized as a synonym for the PRINT statement. This can simplify the creation of certain test code, since the query character provides similar functionality in both compilers.

Restrictions Strings displayed by the MSGBOX function are displayed only up to the first $NUL character, if any.

See also INPUTBOX$, MSGBOX function, TXT pseudo-object

Example

```
MSGBOX "Got here, hit OK to continue",, "Title of subroutine 123"
MSGBOX "Current value of X% is: " & STR$(x%)
MSGBOX "Paused, click OK to continue!"
MSGBOX "Click OK to reboot the universe…", %MB_TASKMODAL OR %MB_ICONERROR,
"Reality has crashed!"
```

MYBASE pseudo-variable

Keyword Template

Purpose

Syntax

Remarks

See also

Example

MYBASE pseudo-variable

Purpose A pseudo object variable to reference the inherited parent object.

Syntax `MYBASE.Method1(param)`

Remarks MYBASE is a pseudo-variable, which PowerBASIC automatically defines in every Method and Property on an inherited interface. It is treated as a reference to the original, inherited object. Using MYBASE, it's possible to call the original Methods and Properties so you can modify or build upon them in the derived interface.

MYBASE may not be assigned to an object variable, nor may it be used as a Sub/Function/Method/Property parameter.

See also CLASS, INTERFACE (Direct), INTERFACE (IDBind), ME, METHOD, PROPERTY, What is an object, anyway?, What is inheritance?

NAME statement

NAME statement

Purpose Rename a file or a directory (like the DOS REN command).

Syntax `NAME filespec1$ AS filespec2$`

Remarks The NAME statement comprises the following elements:

filespec1$* The current name of a file or directory. The file must not be currently opened or locked. *filespec1$ may be either a Short File Name (SFN) or a Long File Name (LFN).

filespec2$ The desired name of the file or directory, and may use Long File Name (LFN) naming conventions.

Each filespec may contain drive and path specifications as well as a file or directory name.

If *filespec1* does not exist, run-time Error 53 ("File not found") occurs. If *filespec2* already exists, run-time Error 58 occurs ("File already exists"). If *filespec1* has been opened or locked by your application and not closed, an Error 51 can occur ("Internal system error"). You should never rename a file that has been opened by your code and not (yet) closed.

Restrictions It is possible to move a file from one directory, drive, or partition, to another. It is not possible to move directories between drives or partitions. Wildcard characters are not permitted in the file names.

Example

```
OldName$ = "MYFILE.EXE"
NewName$ = "YOURFILE.EXE"
NAME OldName$ AS NewName$
```

NEXT statement

FOR/NEXT statements

Purpose Define a loop of program statements whose execution is controlled by an automatically incrementing or decrementing counter.

Syntax

```
FOR Counter = start TO stop [STEP increment]
  [statements]
  [EXIT FOR]
  [statements]
  [ITERATE FOR]
  [statements]
NEXT [Counter]
```

Remarks *Counter* is a numeric variable serving as the loop counter.

start is a numeric expression specifying the value initially assigned to *Counter*.

stop is a numeric expression giving the value that *Counter* must reach for the loop to be terminated.

increment is an optional numeric expression defining the amount by which *Counter* is incremented with each loop execution. If not specified, *increment* defaults to 1.

Note that *increment* must be the same data type or in the same range as *Counter*. For example:

```
FOR x?? = 50 TO 1 STEP -1
```

will fail because -1 is not within the range of an unsigned Word variable.

When a FOR statement is encountered, *start* is assigned to *Counter,* and *Counter* is tested to see if it is greater than (or, for negative *increment*, less than) *stop*. If not, the statements within the FOR/NEXT loop are executed, *increment* is added to *Counter*, and *Counter* again tested against *stop*. The statements in the loop are executed repeatedly until the test fails, at which time control passes to the statement immediately following the NEXT.

If *increment* is equal to the maximum value of a variable class (255 for a byte, 32767 for an Integer, 65535 for a Word, etc), the compiler will generate an error. If *step* is zero, an infinite loop can be created.

When using

values with FOR/NEXT, be sure to allow for round-off errors when mixing numbers of different precision. Using constants or variables of the same type throughout will help solve this problem:

```
FOR n# = 1.0 TO 1.5 STEP 0.1
  x$ = STR$(n#)
NEXT n#
```

executes 5 times and returns:

```
1
1.10000000149012
1.20000000298023
1.30000000447035
1.40000000596046
```

while:

```
FOR n@ = 1.0@ TO 1.5@ STEP 0.1@
  x$ = STR$(n@)
NEXT n@
```

executes 6 times and returns:

```
1
1.1
1.2
1.3
1.4
1.5
```

FOR/NEXT loops run fastest when *Counter* is a Long-integer variable, and *start* and *increment* are Long-integer constants. The value of *Counter* is available like any other variable within the loop. It is wise to avoid explicitly modifying the value of *Counter* within the loop. If you need to exit the loop prematurely, use an EXIT FOR statement. Keep range considerations in mind. For example, if *Counter* is an Integer variable, you may not use the maximum value for an Integer for *stop*, as *Counter* would be incremented outside the Integer range at the end of the loop.

The body of the loop is skipped altogether if the initial value of *Counter* is greater than *stop* (or, for a negative *increment*, if *Counter* is less than *stop*).

FOR/NEXT loops can be nested within other FOR/NEXT loops. Be sure to use unique counter variables. Note that PowerBASIC allows the *Counter* in the NEXT keyword simply as a comment, which is ignored. For example, the following will compile, even though the counter variables are "crossed":

```
FOR n = 1 TO 10
  FOR m = 1 TO 20
    .
    .
    .
  NEXT n
NEXT m
```

You can omit the counter variable in the NEXT statement altogether. For example:

```
FOR n = 1 TO 10
  .
  .
  .
NEXT
```

If a NEXT is encountered without a corresponding FOR (or vice versa), a compile-time error is generated.

> **Previous version of PowerBASIC supported a single NEXT statement used with multiple nested FOR/NEXT loops, such as NEXT c, b, a. This is no longer supported and you will need to update your code to use multiple NEXT statements.**

In certain situations, previous versions of PowerBASIC optimized FOR/NEXT loops to count down instead of up for improved execution speed. This optimization could cause the counter variable to contain a value which was not expected when execution of the loop was complete. This optimization has been improved so that the counter variable value is always correct upon loop completion, even if EXIT FOR was used to force an early termination.

Although the compiler does not care about such things, it is considered good programming practice to indent the statements between FOR and NEXT by two or three spaces to set off the structure of the loop.

For additional performance, use a REGISTER variable for the loop counter variable.

Restrictions The counter variable must be a simple numeric scalar variable, such as LOCAL, STATIC, GLOBAL, or REGISTER. This aids in maintaining high performance levels for a simple loop structure. Variables which require multiple operations to access are specifically disallowed: THREADED, INSTANCE,

Parameters, POINTER Targets, and ARRAY.

See also #OPTIMIZE, #REGISTER, DO/LOOP, EXIT, FOR EACH/NEXT, ITERATE, WHILE/WEND, REGISTER

NOT operator

NOT operator

Purpose The NOT operator works as a bitwise arithmetic operator.

Syntax `NOT p`

Remarks PowerBASIC's NOT operator returns the one's-complement of an

expression. When dealing with the absolute values 0 and -1, the NOT operator "reverses" the two values, performing a Boolean-like operation.

PowerBASIC accepts any non-zero value as a logical TRUE value; therefore, subtle logic problems can arise in a program when the NOT operator is used to perform Boolean logic tests with operand values that are not limited to just 0 and -1.

Consider the following two test conditions:

```
test1 = 0          ' test1 is FALSE (zero)
IF NOT test1 THEN  ' TRUE (-1 is non-zero)

test2 = 1          ' test2 is TRUE (1 is non-zero)
IF NOT test2 THEN  ' still TRUE (-2 is non-zero)
```

Because NOT performs a bitwise operation on *test2*, it does not reverse the logical TRUE/FALSE value of *test2*, rather, it returns -2 (the one's-complement of 1) and this is evaluated as a logical TRUE value.

In cases where a proper logical (Boolean) evaluation is required, and the operand may be a value other than 0 and -1, the ISFALSE operator should be used in place of the NOT operator:

```
test3 = 1             ' test3 is TRUE (non-zero)
IF ISFALSE test3 THEN ' ISFALSE detects test3 is
[statements]          ' TRUE so the IF test fails
```

The two's-complement of a value can be obtained with the following algorithm:

```
y = (NOT x) + 1
Using NOT as a logical operator
```

NOT returns 0 (FALSE) if *and only if* its operand is *exactly* -1 (TRUE). Generally, you should use the ISFALSE operator instead of NOT, when you are testing for logical falsity.

Truth table

x	NOT x
0	-1
-1	0

Using NOT as a bitwise arithmetic operator

NOT performs a one's-complement or bit reversal of each bit in an integral-class value. Here is a sample:

```
x% = NOT 16383%  ' Result is -16384
```

```
NOT        0011 1111 1111 1111  (&H3FFF)
           1100 0000 0000 0000  (&HC000)
MSB                             LSB (bit 0)
```

See also Arithmetic Operators, AND, EQV, IMP, ISFALSE, ISTRUE, OR, Short-circuit evaluation, XOR

NUL$ function

NUL$ function

Purpose Return a

consisting of a specified number of $NUL (CHR$(0)) characters.

Syntax `sResult$ = NUL$(count)`

Remarks NUL$ returns a *count* character string of $NUL characters.

See also CHR$, REPEAT$, SPACE$, STRING$

OBJACTIVE function

OBJACTIVE function

Purpose Return TRUE/FALSE as an indication of the running state of an initialized COM object (EXE based).

Syntax `lResult& = OBJACTIVE(prgid$)`

Remarks OBJACTIVE can provide information that may prove useful in determining whether to use the NEWCOM or GETCOM options with the LET (with Objects) statement. OBJACTIVE may only be used on COM objects that are in EXE format, not DLL/OCX/etc. In the latter case, OBJACTIVE returns FALSE (0).

*prgid$* The registered program ID string for the COM object. For example, "Word.Application.8", or a version-independent program ID such as "Word.Application". A valid program ID string can be obtained from a 16-byte class ID string using the PROGID$ function, or derived from a 38 character GUID string using PROGID$ and GUID$.

See also DIM, CLSID$, GUID$, GUIDTXT$, INTERFACE (Direct), INTERFACE (IDBind), ISNOTHING, ISOBJECT, Just what is COM?, LET (with Objects), OBJECT, OBJEQUAL, OBJPTR, OBJRESULT, PROGID$, What is a COM component?

Example

```
' Create a reference to the MSWORD object
LOCAL oWord AS IDISPATCH  ' use late-binding
LOCAL i     AS LONG

IF OBJACTIVE("Word.Application") THEN
  ' Word is already active, use the existing instance
  oWord = GETCOM "Word.Application"
ELSE
  ' Word is not active, create a new instance
  oWord = NEWCOM "Word.Application"
END IF
' Set MS Word to a normal visible state
i = 0
OBJECT LET oWord.WindowState = i
' more code here
```

OBJECT statement

OBJECT statement

Purpose Communicate with a COM object through the dispatch interface.

Syntax

```
OBJECT GET interface.member[.member.] [([[paramname =] param1 [, ...]])]
TO ResultVar
OBJECT LET interface.member[.member.] [([[paramname =] param1 [, ...]])] =
ValueVar
OBJECT SET interface.member[.member.] [([[paramname =] param1 [, ...]])] =
ValueVar
OBJECT CALL interface.member[.member.] [([[paramname =] param1 [, ...]])]
[TO ResultVar]
OBJECT RAISEEVENT [interface.]member[([[paramname =] param1 [, ...]])]
```

Remarks There are five general forms of the OBJECT statement which are used to communicate through a Dispatch interface to an object.

OBJECT GET	Retrieve or read the value of an Interface member Property. This is similar to retrieving the value of a variable.
OBJECT LET	Assign or write a value to an Interface member Property. This is similar to assigning a value to a variable.
OBJECT SET	Assign or write a value to an Interface member Property that contains a reference to an object. For example, a reference to another Interface.
OBJECT CALL	Call or execute a member Method of an Interface. This is equivalent to calling a Sub or Function.
OBJECT RAISEEVENT	Call or execute a member Method of a Dispatch event Interface. Because the Dispatch event interface is pre-defined, you are not required to specify the interface name in this form

of the statement. However, including it aids in self-documentation of your program. If your program is using a Direct, V-Table event handler you should use the RAISEEVENT statement instead. See the EVENT SOURCE statement for an OBJECT RAISEEVENT example.

All parameters, return values, and assignment values must be in the form of COM-compatible variables. Literals and expressions are not allowed. COM-compatible variables include BYTE, WORD, DWORD, INTEGER, LONG, QUAD, SINGLE, DOUBLE, CURRENCY,

, and VARIANT. You should use caution passing string data since COM Objects require that unicode format be used. When string data is contained in a VARIANT variable, conversion to/from unicode is automatic, and no intervention is needed from the programmer. However, if you pass data in a dynamic string variable, you must use the ACODE$() and UCODE$() functions to convert the data to an appropriate format. For this reason, we recommend that string data be passed using VARIANT variables.

Dispatch OBJECT Method calls may be bound at run-time using late binding, which requires no declaration of Properties and Methods. However, for this very reason, the validity of these references can not be verified by PowerBASIC at the time the program is compiled.

The OBJECT statement can use both positional and named parameters, but you should keep in mind that not all COM Dispatch Servers support named parameters. Positional parameters are universally supported.

A positional parameter is simply a variable containing an appropriate value. It is identified by its position in the parameter list, just as in a traditional SUB or FUNCTION. A named parameter consists of a parameter identifier (a name), an equal (=) sign, and a variable containing an appropriate value. Positional parameters must precede any and all named parameters, but named parameters may be specified in any sequence.

Each time you call a Method or Property using the OBJECT statement, a status code is returned in a hidden parameter to indicate the success or failure of the operation. You can retrieve information about this status code with the OBJRESULT function, and also by using the IDISPINFO Dispatch Information Object. If the failure was severe, then a PowerBASIC error 99 (Object Error) is also generated and the ERR system variable is set. You can find more information about these items by referring to OBJRESULT, IDISPINFO, and ERR. This information can be very useful for both debugging and handling run-time errors.

Restrictions

All parameters, return values, and assignment values must be in the form of COM-compatible variables. Use of the wrong member mode (GET/LET/SET/CALL/RAISEEVENT) can sometimes result in unexpected and fatal run-time errors. So, it's usually prudent to test the result code in OBJRESULT after every OBJECT statement.

```
' Assumes Interface definitions have been
' declared for the Microsoft Agent Control
LOCAL AgentCtrlEx  AS IAgentCtlEx
LOCAL  StartX      AS LONG
LOCAL  StartY      AS LONG
LOCAL  CharW       AS LONG
LOCAL  CharH       AS LONG
LOCAL  Connected   AS LONG
LOCAL  AgentName   AS STRING
```

```
LOCAL   AgentFile   AS STRING

' Create a new instance of the COM Object
AgentCtrlEx = NEWCOM $PROGID_Agent2
IF ISFALSE(ISOBJECT(AgentCtrlEx)) THEN EXIT FUNCTION

' Set the connected property
Connected = 1
OBJECT LET AgentCtrlEx.Connected = Connected

' Load the Merlin Agent Character
AgentName = UCODE$("Merlin")
AgentFile = UCODE$("Merlin.acs")
OBJECT CALL AgentCtrlEx.Characters.Load(AgentName, AgentFile)

' Display the Merlin Agent Character on the screen
OBJECT CALL AgentCtrlEx.Characters.Character(AgentName).Show

' Find the center of the screen for the Character Agent
OBJECT GET AgentCtrlEx.Characters.Character(AgentName).Width  TO CharW
OBJECT GET AgentCtrlEx.Characters.Character(AgentName).Height TO CharH
DESKTOP GET CLIENT TO StartX, StartY
StartX = (StartX - CharW)\2
StartY = (StartY - CharH)\2

' Move the Character to the center of the screen
OBJECT CALL AgentCtrlEx.Characters.Character(AgentName).MoveTo(StartX,
StartY)
' more code here
```

OBJEQUAL function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

OBJEQUAL function New!

Purpose Check if object variables refer to the same object.

Syntax `Result = OBJEQUAL(ObjectVar1, ObjectVar2)`

Remarks Compares two object variables to determine if they refer to the same object. It returns true (-1) if both refer to the same object (or both refer to NOTHING); otherwise it returns false (0).

If the two object variables refer to the same class, but not the same specific object, false (0) is returned.

See also BITSE

OBJPTR function

OBJPTR function

Purpose Return an object pointer contained in the specified object variable.

Syntax `ObjectPointer??? = OBJPTR(objectvar)`

Remarks OBJPTR returns the object pointer as a Double-word (DWORD) value.

See also DIM, CLSID$, GUID$, GUIDTXT$, INTERFACE (Direct), INTERFACE (IDBind), ISINTERFACE, ISNOTHING, ISOBJECT, LET (with Objects), OBJECT, OBJACTIVE, OBJEQUAL, OBJRESULT, PROGID$, What is an object, anyway?

OBJRESULT function

OBJRESULT function

Purpose Returns a status code (hResult) to describe the success or failure of the most recent METHOD or PROPERTY procedure.

Syntax `lResult& = OBJRESULT`

Remarks An Automation procedure is a METHOD or PROPERTY on an IAUTOMATION, IDISPATCH, or DUAL interface. By definition, an Automation procedure always returns a hidden result code which is cryptically called an hResult. OBJRESULT the most recent hResult generated by the program, and can be used to identify the success or failure of an operation.

If an Automation procedure fails with a severe error, the ERR system variable is set to an appropriate PowerBASIC error code. This is usually Error 99 ("Object error"). In such cases, you can use the OBJRESULT function to return the result (hResult&) of the last run-time OBJECT statement or direct METHOD/PROPERTY reference.

Numeric equates for most OBJRESULT errors can be found in the WIN32API.INC file, and are mostly prefixed with %E_, %CO_, %OLE_, and %DISP_. The following list includes the most common codes that may be returned by a direct call of a Method or Property:

```
%S_OK                    = &H0
%S_FALSE                 = &H1
%E_UNEXPECTED            = &H8000FFFF&
%E_NOTIMPL               = &H80004001&
%E_NOINTERFACE           = &H80004002&
%E_POINTER               = &H80004003&
%E_ABORT                 = &H80004004&
%E_FAIL                  = &H80004005&
%E_ACCESSDENIED          = &H80070005&
%E_HANDLE                = &H80070006&
%E_OUTOFMEMORY           = &H8007000E&
%E_INVALIDARG            = &H80070057&
```

This list tells the most common status codes which may be returned by a DISPATCH call using the OBJECT statement:

```
%S_OK                    = &H0
%DISP_E_ARRAYISLOCKED    = &H8002000D
%DISP_E_BADINDEX:        = &H8002000B
%DISP_E_BADPARAMCOUNT    = &H8002000E
%DISP_E_BADVARTYPE       = &H80020008
%DISP_E_EXCEPTION        = &H80020009
%DISP_E_MEMBERNOTFOUND   = &H80020003
%DISP_E_NONAMEDARGS      = &H80020007
%DISP_E_OVERFLOW         = &H8002000A
```

```
%DISP_E_PARAMNOTFOUND     = &H80020004
%DISP_E_TYPEMISMATCH      = &H80020005
%DISP_E_UNKNOWNINTERFACE = &H80020001
%DISP_E_UNKNOWNLCID       = &H8002000C
%DISP_E_UNKNOWNNAME       = &H80020006
%DISP_E_PARAMNOTOPTIONAL = &H8002000F
```

If the status code %DISP_E_EXCEPTION is returned, you can use the IDISPINFO object to secure much additional information about the status. This includes a more specific error code, a description, help file information, etc. If the status code %DISP_E_PARAMNOTFOUND or %DISP_E_TYPEMISMATCH, you can use IDISPINFO.PARAM to determine which parameter actually caused the problem. Please refer to the IDISPINFO section for more details.

As can be seen from the above lists, a large numeric status code can be cryptic. However, you can translate the OBJRESULT code into a descriptive message using the OBJRESULT$ function. This can be most helpful, especially during application development and debugging.

Restrictions Methods and Properties on a custom interface (a direct interface based upon IUnknown rather than IDispatch) do not support OLE Automation, and do not return an OBJRESULT (hResult).

See also DIM, CLASS, CLSID$, IDISPINFO, GUID$, GUIDTXT$, INTERFACE (Direct), INTERFACE (IDBind), ISINTERFACE, ISNOTHING, ISOBJECT, LET (with Objects), METHOD, PROPERTY, OBJECT, OBJACTIVE, OBJEQUAL, OBJPTR, OBJRESULT$, PROGID$, What is an hResult?, What is an object, anyway?

OBJRESULT$ function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

OBJRESULT$ function

Purpose Returns a string which describes an OBJRESULT (hResult) code.

Syntax ***text$*** **= OBJRESULT$([*nexp&*])**

Remarks This function returns a text

which describes the hResult code specified by *nexp&*. If the parameter *nexp&* is omitted, it is replaced by the most recent OBJRESULT value. That is, OBJRESULT$() is identical to OBJRESULT$(OBJRESULT).

See also DIM, CLASS, CLSID$, IDISPINFO, GUID$, GUIDTXT$, INTERFACE (Direct), INTERFACE (IDBind), ISINTERFACE, ISNOTHING, ISOBJECT, LET (with Objects), METHOD, PROPERTY, OBJECT, OBJACTIVE, OBJPTR, OBJRESULT, PROGID$, What is an hResult?, What is an object, anyway?

OCT$ function

OCT$ function IMPROVED

Purpose Convert an integral value to an octal

.

Syntax `s$ = OCT$(IntVal [, Digits, LeadSpaces, TrailSpaces])`

Remarks *IntVal* is a

expression in the range of a 64-bit Quad Integer (-9223372036854775808 to +9223372036854775807). Any fractional part of the value is rounded. The result string is always formatted as an integral number using all the significant digits in *IntVal*. It is never expressed in scientific notation.

If *Digits* is 0 (or not given), no leading characters will be added to the numeric field. If *Digits* is a positive number greater than 0, the result string will be prepended with leading zeros to achieve the desired length. If *Digits* is a negative number, leading spaces are added to reach the absolute length. *Digits* may be in the range of -22 to +22.

LeadSpaces specifies additional leading spaces to be prepended, regardless of the length of the numeric portion of the string.

TrailSpaces specifies additional trailing spaces to be appended to the end of the string.

See also BIN$, DEC$, FORMAT$, HEX$, STR$, TRIM$, USING$, VAL

OemToChr$ function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

OemToChr$ function New!

Purpose Translates a byte

of OEM characters into ANSI/WIDE characters.

Syntax
```
a$ = OemToChr$(OemExpr$)
a$$ = OemToChr$(GRAPHIC, OemExpr$)
```

Remarks *OemExpr$* contains a series of byte (8-bit) characters in OEM format. OemToChr$ translates it into either ANSI multi-byte equivalent characters or WIDE (16-bit) Unicode characters, depending upon the context of the source code. PowerBASIC will always choose the correct form with no intervention needed by the programmer. Control codes, CHR$(0) to CHR$(31) and CHR$(127), are handled uniquely, as they are normally considered to be non-printing characters. By default, they are just copied, without any translation.

GRAPHIC If the option GRAPHIC is included, it indicates you want to convert control codes into the codes which will display the graphic symbols defined in the original IBM OEM character set. Most of these codes are only available as wide Unicode characters.

See also ChrToOem$, ChrToUtf8$, Utf8ToChr$

ON ERROR statement

ON ERROR statement

Purpose Specify an error handling routine; enable or disable error trapping.

Syntax

```
ON ERROR GOTO {label | line_number}
ON ERROR RESUME NEXT
ON ERROR GOTO 0
```

Remarks *label* or *line_number* identifies the first line of the error trapping routine. Once error handling has been turned on with this statement, all run-time errors result in a jump to your error handling code. When the error handler begins execution, additional error trapping is temporarily suspended. When your error handling is complete, you must use the RESUME statement (any form) to continue execution. RESUME reactivates the temporary suspension of error trapping.

You must use additional care when you trap an error within a GOSUB block of code, because a RETURN address has been saved on the system stack. If you use a form of RESUME which re-enters the GOSUB block, a RETURN will still be executed later, and the stack will be balanced. However, if RESUME <Label> or RESUME FLUSH redirects execution elsewhere, you must use RETURN FLUSH to remove the return address from the stack.

To disable error trapping, use ON ERROR GOTO 0 or ON ERROR RESUME NEXT. You can use this technique if an error occurs for which you have not defined a recovery path; you can also choose to display the contents of ERR or ERRCLEAR at this time.

The default for error trapping is disabled. If an error occurs while error trapping is disabled, the error code is placed into the ERR system variable, and execution continues. Errors can still be trapped by checking the value of the ERR or ERRCLEAR variable with

ERR THEN or SELECT CASE ERR statements.

Error trapping is local to each Sub, Function, Method, and Property. PowerBASIC does not support global error trapping.

Numeric errors such as Divide-by-zero, Overflow and Underflow are not trapped. Array out-of-bounds and null-pointer trapping are only enabled if #DEBUG ERROR ON is used.

If you're running a program with error trapping turned off, a run-time error may cause a General Protection Fault (GPF). A GPF cannot be trapped with ON ERROR.

It is not possible to branch to an error handler from within an expression. The compiler tests for an error only after the statement is completed. This means that a statement such as:

```
ON ERROR GOTO ErrorHandlerLabel
IF GETATTR(sFile) THEN
  ' Do something
END IF
```

will generate an Error 53 when *sFile* does not exist, but will not branch to the *ErrorHandlerLabel*. This is because the GETATTR(*sFile*) is an expression in the IF/ END IF block. You could do a

```
ON ERROR GOTO ErrorHandlerLabel
a& = GETATTR(sFile)f
IF a& THEN
  ' Do something
END IF
```

which will branch to the *ErrorHandlerLabel* if *sFile* does not exists. You could also check the value of the ERR variable or use a TRY/ END TRY block to see if an error occurred when checking for errors that occur during an expression.

See also #DEBUG DISPLAY, #DEBUG ERROR, ERR, ERRCLEAR, ERROR, Error Overview, ERROR$, Errors and Error Trapping, RESUME

ON GOSUB statement

ON GOSUB statement

Purpose Call one of several subroutines according to the value of a numeric expression.

Syntax **ON *n* GOSUB {*label* | *line_number*} [, {*label* | *line_number*}] ...**

Remarks *n* is a numeric expression ranging from 1 to 255, and each *label* or *line number* identifies a statement to branch to. When this statement is encountered, the *n*th label in the list is branched to; for example, if *n* equals 4, the fourth label in the list receives control. If *n* is less than one or greater than the number of labels, no branch occurs, and PowerBASIC continues execution with the statement immediately following the ON GOSUB statement.

Each subroutine should end with RETURN, which causes execution to resume with the statement immediately following the ON GOSUB statement. ON GOSUB can only branch to labels or line numbers that have the same scope as the ON GOSUB statement.

The SELECT and IF blocks also perform multiple branching and are more flexible than ON GOSUB.

Note that ON GOSUB (and ON GOTO) have been internally optimized to produce greater run-time performance than was possible with previous versions of PowerBASIC.

See also GOSUB, FUNCTION/END FUNCTION, IF block, METHOD, ON GOTO, PROPERTY, RETURN, SELECT, SUB/END SUB

Example

```
FOR I& = 1 TO 3
  ON I& GOSUB OneHandler, TwoHandler, ThreeHandler
NEXT I&

OneHandler:
  Message$ = "Handler number" + STR$(I&)
  RETURN

TwoHandler:
  Message$ = "Handler number" + STR$(I&)
  RETURN

ThreeHandler:
  Message$ = "Handler number" + STR$(I&)
  RETURN
```

Result

```
Handler number 1
Handler number 2
Handler number 3
```

ON GOTO statement

ON GOTO statement

Purpose Send program flow to one of several possible destinations based on the value of a expression.

Syntax **ON *n* GOTO {*label* | *line_number*} [, {*label* | *line_number*}] ...**

Remarks *n* is a numeric expression ranging from 1 to 255, and *label* or *line_number* identifies a statement in the program to branch to. The *n*th label is branched to; for example, if *n* equals 4, the fourth label in the list receives control. If *n* is less than one or greater than the number of labels in the list, program execution continues with the statement that immediately follows the ON GOTO statement.

ON GOTO behaves exactly like ON GOSUB, except that it performs a GOTO rather than a GOSUB. This means that the program retains no memory of where the branch originated. ON GOTO can only branch to labels or line numbers that have the same scope as the ON GOTO statement.

The SELECT and IF blocks also perform multiple branching, and are more flexible than ON GOTO. See the GOTO entry for a discussion of ways to avoid using GOTOs in your programs.

Note that ON GOTO (and ON GOSUB) have been internally optimized to produce greater run-time performance than was possible with previous versions of PowerBASIC.

See also GOTO, IF block, ON GOSUB, SELECT

Example

```
SUB MainEx
  FOR I& = 1 TO 3
    ON I& GOTO OneHandler, TwoHandler, ThreeHandler
    Back:
  NEXT I&
  EXIT SUB

OneHandler:
  Message$ = "Handler number" + STR$(I&)
  GOTO Back

TwoHandler:
  Message$ = "Handler number" + STR$(I&)
  GOTO Back

ThreeHandler:
  Message$ = "Handler number" + STR$(I&)
  GOTO Back
END SUB
```

Result

```
Handler number 1
Handler number 2
Handler number 3
```

OPEN statement

OPEN statement IMPROVED

Purpose Prepare a file or device for reading or writing.

Syntax

```
OPEN filespec [FOR mode] [ACCESS access] [LOCK lock] AS _
    [#] filenum& [LEN = record_size] [BASE = base] [CHR = ANSI|WIDE]
OPEN HANDLE filehandle [FOR mode] [ACCESS access] [LOCK lock] AS _
    [#] filenum& [LEN = record_size] [BASE = base] [CHR = ANSI|WIDE]
```

Remarks The main function of OPEN is to associate a file number (*filenum&*) with a file or physical device and to prepare that device for reading and/or writing. This file number is then used, rather than its name, in every statement that refers to the file. The FREEFILE function can be used to determine the next unused file number, or you can pick one yourself. An OPEN statement is usually balanced by a matching CLOSE statement. The OPEN statement comprises the following elements:

filespec A string expression specifying the name of the file to be opened, and may optionally include a drive and/or path specification. *filespec* may be either a Short File Name (SFN) or a Long File Name (LFN). *filespec* has a limit of 259 characters (%MAX_PATH - 1), although the file name portion of *filespec* may be no more than 255 characters (%MAX_FNAME - 1).

mode Specifies the file organization and style of access (sequential, random access, or binary) for reading, writing (or both), or appending. If *mode* is not specified, the default is RANDOM access.

Mode	File type	Action
`INPUT`	Sequential	Read from
`OUTPUT`	Sequential	Write to
`APPEND`	Sequential	Append to
`BINARY`	Binary	Reading or writing
`RANDOM`	Random	Reading or writing (default)

access Specifies the type of access this process will have to the file. By default, the file may be written to and read from.

Access	Description
`READ`	Only read operations allowed
`WRITE`	Only write operations allowed
`READ WRITE`	Both read and write operations allowed (default)

Note that APPEND mode requires READ/WRITE access.

lock Specifies the type of access other processes will have to the file. If a LOCK clause is not specified in the OPEN statement, the default LOCK READ WRITE mode is applied. This mode ensures exclusive access to the file, and enables PowerBASIC to optimize its internal buffering for utmost I/O performance. If other processes or threads are to be permitted WRITE access to the file (LOCK SHARED or LOCK READ), internal buffering is disabled. Whilst performance may be marginally lower, it ensures that data read from the file is completely up-to-date.

Lock	Description
`SHARED`	Both read and write operations allowed
`WRITE`	Prevent write operations
`READ`	Prevent read operations
`READ WRITE`	Neither read nor write operations allowed (default)

To open a text file for OUTPUT and allow other processes to only read the file, use the following:

```
OPEN "MYFILE.TXT" FOR OUTPUT LOCK WRITE AS #1
```

It is possible for an application to open more than one copy of a given file at the same time. In this case, each OPEN statement must use a unique file number, and LOCK READ WRITE mode should not be used.

filenum& A unique integer value identifying the file, in the range 1 to 32767. Typically, this value is obtained from the FREEFILE function.

record_size Specifies the size of each record of a random access file. The default record length is 128 if not specified. If *record_size* is specified for a sequential file, it instructs PowerBASIC to use internal buffering to improve I/O performance. A random access file is limited to 32768 bytes per record, to ensure consistent behavior across all Win32 platforms.

base Specifies the number of the first record in a random access file, or the number of the first byte in a sequential or binary file. It can be either zero (0) or one (1). The default value for *base* is 1, if not specified.

Chr Specifies the character mode for this file: ANSI or WIDE (Unicode). Since sequential files consist of text alone, the selected mode is enforced by PowerBASIC. All data read or written to the file is automatically forced to the selected mode, regardless of the type of variables or expressions used. With binary or random files, this specification has no effect, but it may be included in your code for self-documentation purposes.

ANSI characters in the U.S. range of CHR$(0) to CHR$(127) are known as ASCII, and are always represented by a single byte. International ANSI characters in the range of CHR$(128) to CHR$(255) may be followed by one or more additional bytes in order to accurately represent non-U.S. characters. The exact definition of these characters depends upon the character set in use. WIDE characters are always represented by two bytes per character. If the Chr option is not specified, the default mode is ANSI.

HANDLE — The HANDLE option allows you to access files that have already been opened by another process, DLL, or API function. The *filehandle* specified here must be a valid Win32 operating system file handle.

When PowerBASIC closes a file opened with OPEN HANDLE, the Win32 handle is simply detached from the internal PowerBASIC handle table. The file is not physically closed since PowerBASIC did not originally open it. In PowerBASIC, the FILEATTR function can be used to obtain the operating system file handle for a file opened with the OPEN statement.

Restrictions — Attempting to OPEN a file for INPUT that does not exist causes a run-time Error 53 ("File not found"). Attempting to open a file that is locked can result in either an Error 70 ("Permission denied"), or an Error 75 ("Path/file access error").

Similarly, attempting to OPEN a file using a file number that is already in use will result in a run-time Error 55 ("File is already open "). For this reason, programs that use hard-coded file numbers should take special care to close files before the file number is used again. In addition, code that may be used by more than one thread should use FREEFILE and avoid hard-coded file numbers.

If you try to open a nonexistent file for OUTPUT, APPEND, RANDOM, or BINARY operations, a new file is automatically created. For this reason, files on Read-only network drives may only be opened in INPUT mode.

See also — CLOSE, FILEATTR, FILENAME$, FILESCAN, FREEFILE, TCP OPEN, UDP OPEN

Example — This program is divided into five procedures. The difference between each procedure is the mode in which the file is opened, and the way the data in the file is manipulated:

```
SUB SequentialOutput
  ' The file is opened for sequential output,
  ' and some data is written to it.  If the file
  ' exists, it is over-written.
  OPEN "OPEN.DTA" FOR OUTPUT AS #1
  IntegerVar% = 12345
  TempStr$ = "History is made at night."
  WRITE #1, TempStr$, IntegerVar%*2, TempStr$, IntegerVar% \ 2
  CLOSE #1
END SUB  ' end procedure Sequential Output

SUB SequentialAppend
  ' The file is opened for sequential output, and
  ' data in this case is added to the end of file.
  ' If the file does not exist, it is created.
  OPEN "OPEN.DTA" FOR APPEND AS #1
  IntegerVar% = 32123
  TempStr$ = "I am not a number!"
  WRITE #1, TempStr$, IntegerVar% * 0.2
  CLOSE #1
END SUB  ' end procedure Sequential Append

SUB SequentialInput
  ' The file is opened for sequential input,
  ' and data is read from the file.
  DIM a$
  OPEN "OPEN.DTA" FOR INPUT AS #1
  LINE INPUT #1, TempStr$
  TempStr$ = ""
  WHILE ISFALSE EOF(1)  ' check if at end of file
    LINE INPUT #1, a$
    TempStr$ = TempStr$ + a$
  WEND
  CLOSE #1
END SUB  ' end procedure SequentialInput
```

```
SUB BinaryIO
  ' The file is opened for binary I/O. Data is
  ' read 'using GET$. SEEK explicitly moves the
  ' file pointer to 'the end of file, and the
  ' same data is written back to 'the file.
  OPEN "OPEN.DTA" FOR BINARY AS #1
  TempStr$ = ""
  WHILE ISFALSE EOF(1)
    GET$ #1, 1, Char$
    TempStr$ = TempStr$ + Char$
  WEND
  SEEK #1, LOF(1)
  FOR I& = 1 TO LEN(TempStr$)
    PUT$ #1, MID$(TempStr$,I&,1)
  NEXT I&
  CLOSE 1
END SUB  ' end procedure BinaryIO

SUB RandomIO
  ' Open file for random I/O.  GET and PUT read
  ' and write the data.
  OPEN "OPEN.DTA" FOR RANDOM AS #1 LEN = 1
  TempStr$ = ""
  TempSize& = LOF(1)  ' save file size
  ' using GET, read in the entire file
  FOR I& = 1 TO TempSize&
    GET #1, I&, Char$
    TempStr$ = TempStr$ + Char$
  NEXT I&
  ' PUT copies the data in reverse into the
  ' random access file.
  SEEK #1, 1
  FOR I& = TempSize& TO 1 STEP -1
    LSET Char$ = MID$(TempStr$,I&,1)
    PUT #1,, Char$
  NEXT I&
  CLOSE #1
END SUB  ' end procedure RandomIO
```

OPTION EXPLICIT statement

OPTION EXPLICIT statement

Purpose Force explicit declaration of all variables.

Syntax `OPTION EXPLICIT`

Remarks Using OPTION EXPLICIT in a program has the same effect as using the #DIM ALL metastatement. That is, it requires that all variables be declared before they are used.

When this option is used, the compiler generates a compile-time error if a variable or array is used without being explicitly declared.

See also #DIM

OR operator

OR operator

Purpose The OR operator works as both a logical and a bitwise arithmetic operator.

Syntax ***p* OR *q***

Remarks

Using OR as a logical operator

OR returns TRUE (non-zero) if and only if either or both of its operands is TRUE. Here is OR's truth table:

Truth table

x	y	x OR y
T	T	T
T	F	T
F	T	T
F	F	F

Using OR as a bitwise arithmetic operator

An OR mask sets selected bits of an

value without affecting the other bits. To set the most significant 2 bits in &H9700, use OR with a mask of &HC000; that is, the mask contains all 0s, except for the bit positions you wish to force to 1:

```
          1001 0111 0000 0000 = &H9700
OR        1100 0000 0000 0000 = &HC000 (the mask)
---------------------------------------------------
          1101 0111 0000 0000 = &HD700 (result)

MSB                                 LSB (bit 0)
```

PARSE statement

PARSE statement

Purpose Parse an entire

and extract all delimited fields into an array.

Syntax **PARSE *start$*, *target$()* [, {[ANY] *delim$* | BINARY}]**

Remarks PARSE parses the entire string or string expression specified by *start$*, assigning each delimited sub-string to successive elements of *target$*. The array specified by *target$* may be a dynamic string array, a fixed-length string array, or a nul-terminated string array.

The field delimiter is defined by *delim$*, which may be one or more characters long. To be valid, the entire delimiter must match exactly, but the delimiter itself is never assigned as a part of the delimited field.

If *delim$* is not specified or is null (zero-length), standard comma-delimited (optionally quoted) fields are presumed. In this case only, the following parsing rules apply. If a standard field is enclosed in optional quotes, they are removed. If any characters appear between a quoted field and the next comma delimiter, they are discarded. If no leading quote is found, any leading or trailing blank spaces are trimmed before the field is returned.

ANY If the ANY option is chosen, each appearance of any single character comprising *delim$* is considered a valid delimiter.

BINARY The BINARY option presumes that the *string_expr* was created with the JOIN$/BINARY function, or its equivalent, which creates a string as a binary image or in the PowerBASIC and/or Visual Basic packed string format: If a string is shorter than 65535 bytes, it starts with a 2-byte length WORD followed by the string data. Otherwise it will start a 2-byte value of 65535, followed by a DWORD indicating the string length, then finally the string data itself.

It is usually advantageous to dimension *target$* to the correct size with the use of the PARSECOUNT function. The PARSE statement is typically much more efficient, as a whole, than repeated use of the PARSE$ function when it is necessary to parse an entire string expression.

The JOIN$ function is the natural complement to the PARSE statement.

See also JOIN$, PARSE$, PARSECOUNT, PATHNAME$, PATHSCAN$

Example

```
a$ = "Trevor, Bob, Bruce, Dan, Simon, Jenny"
DIM b$(1 TO PARSECOUNT(a$))
PARSE a$, b$()
ARRAY SORT b$()
```

Result

```
b$(1) = "Bob"
b$(2) = "Bruce"
b$(3) = "Dan"
b$(4) = "Jenny"
b$(5) = "Simon"
b$(6) = "Trevor"
```

PARSE$ function

PARSE$ function

Purpose Return a delimited field from a string expression.

Syntax `a$ = PARSE$(string_expr [, {[ANY] string_delimiter | BINARY}], index&)`

Remarks PARSE$ uses the following parameters:

string_expr The

to parse. If *string_expr* is empty (a null string) or contains no delimiter character(s), the string is considered to contain exactly one field. In this case, PARSE$ will return *string_expr*.

string_delimiter Contains delimiter character(s). A delimiter is a character, list of characters, or string, that is used to mark the end of a field in *string_expr*. For example, if you consider a sentence to be a list of words, the delimiter between the works is a space (or perhaps punctuation). Text files typically consist of lines that are delimited by CR/LF ($CRLF or CHR$(13,10)) characters; a database file may consist of items separated by commas; etc. A delimiter is not considered part of a field, but as the divider between fields, so the delimiter is never returned by PARSE$.

If *delim$* is not specified or is null (zero-length), standard comma-delimited (optionally quoted) fields are presumed. In this case only, the following parsing rules apply. If a standard field is enclosed in optional quotes, they are removed. If any characters appear between a quoted field and the next comma delimiter, they are discarded. If no leading quote is found, any leading or trailing blank spaces are trimmed before the field is returned.

Delimiters are case-sensitive, so capitalization may be a consideration.

ANY If the ANY keyword is used, *string_delimiter* contains a set of characters, any of which may act as a delimiter character. If the ANY keyword is omitted, the entire *string_delimiter* string acts as a single delimiter.

BINARY The BINARY option presumes that *string_expr* was created with the JOIN$/BINARY function, or its equivalent, which creates a string as a binary image or in the PowerBASIC and/or Visual Basic packed string format: If a string is shorter than 65535 bytes, it starts with a 2-byte length WORD followed by the string data. Otherwise it will start a 2-byte value of 65535, followed by a DWORD indicating the string length, then finally the string data itself.

index& An

variable or expression that specifies the delimited field number to return. The first field is 1, and so on up to the maximum number of fields contained in *string_expr*, which may be determined with the PARSECOUNT function. If *index&* is negative, *string_expr* is parsed from right to left. In this case, *index&* = -1 returns the last field in *string_expr*, -2 returns the second to last, etc. If *index&* evaluates to zero, or is outside of the actual field count, an empty string is returned.

See also JOIN$, PARSE, PARSECOUNT, PATHNAME$, PATHSCAN$

Example

```
a$ = PARSE$("one,two,three", 2)   ' returns "two"
a$ = PARSE$("one;two,three", 2)   ' returns "three"
a$ = PARSE$("one",2)              ' returns ""
a$ = PARSE$("xyz",1)              ' returns "xyz"
a$ = PARSE$("xx1x","x",3)         ' returns "1"
a$ = PARSE$("1;2,3", ANY ",;", 2) ' returns "2"
```

PARSECOUNT function

PARSECOUNT function

Purpose Return the count of delimited strings in a string expression.

Syntax ***x&*** **= PARSECOUNT(*string_expr* [, {[ANY] *string_delimiter* | BINARY}])**

Remarks PARSECOUNT uses the same rules as PARSE$ in the determination of fields within *string_expr*. Individual fields within *string_expr* are evaluated, and the tally of the fields forms the result value.

It is important to note that PARSECOUNT may only be used with string data which contains variable length sub-fields, each of which is separated by a delimiter. To determine the count of fixed length data, divide the *StringExpr* length by the sub-field length. If this function is used with fixed length data, the results are undefined.

string_expr This is the

to examine and parse. If *StringExpr* is empty (a null string) or contains no delimiter character(s), the string is considered to contain exactly one sub-field. In this case, PARSECOUNT returns the value 1.

string_delimiter This defines one or more characters to use as a delimiter. To be valid, the entire delimiter must match exactly, but the delimiter itself is never returned as part of the field.

If *string_delimiter* is not specified, or contains an empty string, special rules apply. The delimiter is assumed to be a comma. Fields may optionally be enclosed in quotes, and are ignored before the result string is returned. Any characters that appear between a quote mark and the next comma delimiter character are discarded. If no leading quote is found, any leading or trailing quotes are trimmed before the result string is returned.

ANY If the ANY keyword is used, string_delimiter contains a set of characters, any of which may act as a delimiter character. If the ANY keyword is omitted, the entire string_delimiter string acts as a single delimiter.

BINARY The BINARY option returns the number of sub-fields and presumes that *StringExpr* was created with the JOIN$/BINARY function, or its equivalent, which creates a string in the PowerBASIC and/or Visual Basic packed string format: If a string is shorter than 65535 bytes, it starts with a 2-byte length WORD followed by the string data. Otherwise it will start with a 2-byte value of 65535, followed by a DWORD indicating the string length, then the actual string data.

See also JOIN$, PARSE, PARSE$, PATHNAME$, PATHSCAN$

Example

```
a& = PARSECOUNT("one,two,three")    ' returns 3
a& = PARSECOUNT("one;two,three")    ' returns 2
a& = PARSECOUNT("")                 ' returns 1
a& = PARSECOUNT("xx1x","x")         ' returns 4
a& = PARSECOUNT("1;2,3", ANY ",;") ' returns 3
```

PATHNAME$ function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

PATHNAME$ function IMPROVED

Purpose Parse a path/file name to extract component parts

Syntax ***fil$*** **= PATHNAME$(*director*, *filespec$*)**

Remarks The PATHNAME$ function evaluates a text path/file text name, and returns a requested part of the name. The functionality is strictly one of

parsing alone. No attempt is made to find the file on disk. If you wish to scan for a particular file on disk, you should use the companion function PATHSCAN$.

director This is one of the following words which is used to specify the requested part:

FULL	Returns the full path/file name, just as given in the *filespec$* parameter. This is really a non-operation, but is included for symmetry with the companion function PATHSCAN$.
PATH	Returns the path portion of the path/file name. That is the text up to and including the last backslash (\) or colon (:).
NAME	Return the name portion of the path/file name. That is the text to the right of the last backslash (\) or colon (:), ending just before the last period (.).
EXTN	Returns the extension portion of the path/file name. That is the last period (.) in the string plus the text to the right of it.
NAME X	Returns the NAME and the EXTN parts combined.

filespec$ A path/file name which does not necessarily exist on disk.

See also DIR$, EXE, PATHSCAN$, PARSE, PARSE$, PARSECOUNT

Example

```
PATHNAME$(PATH,  "C:\PB\XXX.TXT") ' returns  "C:\PB\"
PATHNAME$(NAME,  "C:\PB\XXX.TXT") ' returns  "XXX"
PATHNAME$(NAMEX, "C:\PB\XXX.TXT") ' returns  "XXX.TXT"
PATHNAME$(EXTN,  "C:\PB\XXX.TXT") ' returns  ".TXT"
```

PATHSCAN$ function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

PATHSCAN$ function

Purpose Find a file on disk and return the path and/or file name parts.

Syntax `fil$ = PATHSCAN$(director, filespec$[, pathspec$])`

Remarks The PATHSCAN$ function scans specified directories to find a particular file. If the file is found, it returns either the full path/file name, or a selected part of it. If the file is not found, a nul (zero-length)

is returned. If you wish to simply parse a text file name, without regard to its validation on disk, you should use the companion function PATHNAME$.

director This is one of the following words which is used to specify the requested part:

FULL	Return the full drive/path/file name.
PATH	Return the path portion of the path/file name. That is the text up to and including the last backslash (\).
NAME	Return the name portion of the path/file name. That is the text to the right of the last backslash (\), ending just before the last period (.) in the string.
EXTN	Return the extension portion of the path/file name. That is the last period (.) in the string plus the text to the right of it.
NAMEX	Return the NAME and the EXTN parts combined.

filespec$ A file name which is expected to exist on disk. It must not be an ambiguous name -- that is, it may not include a query (?) or an asterisk (*) character.

*pathspec$* An optional path string which includes one or more paths to be searched to find filespec$. If multiple path names are included in this string, they must each be separated by a semicolon (;) delimiter. If pathspec$ is not given, or it is a nul (zero-length) string, the following directories are searched:

1. The directory from which the application was loaded.
2. The current directory.
3. The Windows System32 directory.
4. The Windows System16 directory.
5. The Windows directory.
6. The directories in the PATH environment variable.

See also DIR$, EXE, PATHNAME$, PARSE, PARSE$, PARSECOUNT

Example The following information assumes that the file named "MyFile.txt" currently exists in the directory "C:\PB".

```
f$ = "MyFile.txt" : p$ = "C:\MyDir;C:\PB"

PATHSCAN$(FULL, f$, p$) ' returns  "C:\PB\MyFile.txt"
PATHSCAN$(PATH, f$, p$) ' returns  "C:\PB\"
PATHSCAN$(NAME, f$, p$) ' returns  "MyFile"
PATHSCAN$(EXTN, f$, p$) ' returns  ".txt"
PATHSCAN$(NAMEX,f$, p$) ' returns  "MyFile.txt"
```

PBLIBMAIN function

PBLIBMAIN function

Purpose PBLIBMAIN performs a similar task to DLLMAIN and LIBMAIN, except that PBLIBMAIN takes no parameters.

> **In 32-bit Windows, PBLIBMAIN is called each time a DLL is loaded or unloaded by an application or process, and (usually) if a thread is started and stopped. Your code should never call PBLIBMAIN.**

Syntax
```
FUNCTION PBLIBMAIN [()] [AS LONG]
```

Remarks See LIBMAIN / DLLMAIN for more information.

See also DLLMAIN, LIBMAIN, PBMAIN, THREAD CREATE, WINMAIN

PBMAIN function

PBMAIN function

Purpose PBMAIN is a user-defined function called by Windows to begin running an executable application. Every PowerBASIC executable (EXE) must contain either a PBMAIN or a WINMAIN function.

Syntax
```
FUNCTION PBMAIN [()] [AS LONG]
```

Remarks Either a PBMAIN or WINMAIN function is required in every PowerBASIC application (.EXE). If you use PBMAIN, no parameters are passed, and you cannot directly obtain the instance handle of your application or the pointer to any command-line parameters.

However, you can use COMMAND$ to get the command-line passed to your program, and the GetModuleHandle API function to get the application instance handle.

Return The return value of PBMAIN has an effective range of 0 to 255. Batch files may act on the result through the IF [NOT] ERRORLEVEL batch command.

Restrictions DLLs created with PowerBASIC should contain a DLLMAIN, LIBMAIN, or PBLIBMAIN function instead of PBMAIN/WINMAIN.

See also COMMAND$, DLLMAIN, LIBMAIN, PBLIBMAIN, WINMAIN

Example
```
#COMPILE EXE
FUNCTION PBMAIN
  MSGBOX "This is my program!"
  'Return an error level of 15
  FUNCTION = 15 ' or you can use PBMAIN = 15
END FUNCTION
```

PEEK function

PEEK, PEEK$, and PEEK$$ functions IMPROVED

Purpose Returns a byte or sequence of bytes at a specified memory location.

Syntax
```
numvar  = PEEK([datatype,] address???)
ansivar = PEEK$([STRINGZ,] address???, count&)
widevar = PEEK$$([WSTRINGZ,] address???, count&)
```

Remarks The PEEK functions and complementary POKE statements are low-level methods of accessing individual bytes in memory. The data is retrieved from memory, starting at the specified 32-bit *address???*.

PEEK retrieves a

value starting at a specified memory address.

PEEK$ retrieves *count&* consecutive bytes and returns them as a

. If STRINGZ (or ASCIIZ) is specified, PEEK$ reads successive characters from memory, up to the specified size, until a terminating $NUL (CHR$(0)) byte is found. Since STRINGZ strings must contain a terminating $NUL, the maximum length of the returned string is 1 character less than *count&*.

PEEK$$ retrieves *count&* consecutive 2-byte wide characters, and returns them as a wide character string. If WSTRINGZ is specified, PEEK$$ reads successive characters from memory, up to the specified size, until a terminating $NUL (CHR$(0)) character is found. Since WSTRINGZ strings must contain a terminating $NUL, the maximum length of the returned string is 1 character less than *count&*.

Contrary to intuitive notions, PEEK and POKE execute at the same high performance levels as pointer variables. They offer an excellent alternative to pointers in many situations.

datatype The numeric data type to retrieve, which may be any one of BYTE, WORD, DWORD, INTEGER, LONG, QUAD, SINGLE, DOUBLE, EXT, CUR, CUX. If a data type is not specified, BYTE is assumed.

address??? A valid 32-bit memory address specifying the location in memory where data retrieval should begin.

count& A numeric expression that specifies the number of consecutive characters to be read from memory.

Restrictions If *address???* (or any memory in the range covered by *count&*) references an invalid address (memory that is not allocated to the application), Windows will generate a General Protection Fault (GPF) and terminate the application. GPFs cannot be trapped with an ON ERROR error handler.

See also , POKE, STRPTR, VARPTR

Example One common application for PEEK$ and POKE$ is to perform fast array and memory block copy operations by simply copying the entire block of memory which contains the array data, rather than storing each element individually with an assignment statement:

```
Elements& = 2000  ' 2000 elements in each array
DIM OriginalArray%(1 TO Elements&)
DIM NewArray%(1 TO Elements&)

'Method 1: assign each element individually
FOR Index& = 1 TO Elements&
  NewArray%(Index&) = OriginalArray%(Index&)
NEXT Index&

'Method 2: block copy with PEEK$ and POKE$ (faster)
Source&   = VARPTR(OriginalArray%(1))
Dest&     = VARPTR(NewArray%(1))
ArrayLen& = Elements& * 2     'byte length of array
POKE$ Dest&, PEEK$(Source&, ArrayLen&)  'copy block
```

PEEK$ function

PEEK, PEEK$, and PEEK$$ functions IMPROVED

Purpose Returns a byte or sequence of bytes at a specified memory location.

Syntax

```
numvar  = PEEK([datatype,] address???)
ansivar = PEEK$([STRINGZ,] address???, count&)
widevar = PEEK$$([WSTRINGZ,] address???, count&)
```

Remarks The PEEK functions and complementary POKE statements are low-level methods of accessing individual bytes in memory. The data is retrieved from memory, starting at the specified 32-bit *address???*.

PEEK retrieves a

value starting at a specified memory address.

PEEK$ retrieves *count&* consecutive bytes and returns them as a

. If STRINGZ (or ASCIIZ) is specified, PEEK$ reads successive characters from memory, up to the specified size, until a terminating $NUL (CHR$(0)) byte is found. Since STRINGZ strings must contain a terminating $NUL, the maximum length of the returned string is 1 character less than *count&*.

PEEK$$ retrieves *count&* consecutive 2-byte wide characters, and returns them as a wide character string. If WSTRINGZ is specified, PEEK$$ reads successive characters from memory, up to the specified size, until a terminating $NUL (CHR$(0)) character is found. Since WSTRINGZ strings must contain a terminating $NUL, the maximum length of the returned string is 1 character less than *count&*.

Contrary to intuitive notions, PEEK and POKE execute at the same high performance levels as pointer variables. They offer an excellent alternative to pointers in many situations.

datatype The numeric data type to retrieve, which may be any one of BYTE, WORD, DWORD, INTEGER, LONG, QUAD, SINGLE, DOUBLE, EXT, CUR, CUX. If a data type is not specified, BYTE is assumed.

address??? A valid 32-bit memory address specifying the location in memory where data retrieval should begin.

count& A numeric expression that specifies the number of consecutive characters to be read from memory.

Restrictions If *address???* (or any memory in the range covered by *count&*) references an invalid address (memory that is not allocated to the application), Windows will generate a General Protection Fault (GPF) and terminate the application. Dest&     = VARPTR(NewArray%(1))
ArrayLen& = Elements& * 2     'byte length of array
POKE$ Dest&, PEEK$(Source&, ArrayLen&)  'copy block
```

PLAY WAVE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

PLAY statement New!

Purpose Play a sound under program control.

Syntax

```
PLAY WAVE  ResourceID$  [,descriptors...]  [TO ResultVar&]
PLAY WAVE END
```

Remarks The PLAY statement allows you to play a previously created WAVE resource or WAVE file. It's generally advantageous to use the resource form. Access is typically faster and the need for extra files is reduced. The first form of PLAY WAVE starts the sound, while PLAY WAVE END stops any waveform sound which is currently playing.

ResourceID$ is a string expression which tells either the Resource ID of the waveform data, or the disk file where it can be found. If the resource ID is numeric, just precede the number with #, such as "#12345". If the Resource ID contains a period, it is presumed to be the name of a disk file. Otherwise, an attempt is made to load it from a resource -- if not found, it is then presumed to be a disk file. If the waveform data cannot be found, an error 53 (File Not Found) is generated.

If you include the optional TO clause, a success value is assigned to the *ResultVar&*. If the operation succeeds, the value True (non-zero) is assigned. If it fails, the value False (zero) is assigned.

The default method is to play the waveform data in the background. That is, the Play statement returns immediately so the application can execute other code while the sound is playing.

By default, the new sound takes precedence over any other sound currently playing. When PLAY WAVE is executed, any other sound playing is stopped immediately. The new sound is played to replace it. This default methodology can be altered with options described later.

The optional descriptor words (one or more) may be added to control the way in which the sound is played. The descriptors available are:

Loop	The sound is played repeatedly in the background. It plays forever, until PLAY WAVE END is executed, or the program terminates.
NoStop	If another sound is playing, the new sound is discarded and not played. The value False (zero) is returned to the *ResultVar&* to let you know that the operation failed. You can try again to play the new sound at your convenience.
Synch	The sound plays in synchronous mode, commonly known as the foreground. The application waits for the sound to complete before continuing execution of other code. The sound and the code are synchronized.
YieldMS(*TimeOut&*)	If another sound is playing, the new sound yields and allows the first sound to complete. The numeric expression *TimeOut&* tells the maximum number of milliseconds (approximate) to wait before giving up. If the Timeout period expires and the first sound is still playing,

the new sound is aborted. If the Timeout period is zero (0), the program will wait an unlimited amount of time for the first sound to finish. The maximum *TimeOut&* permitted is one hour.

POKE statement

POKE, POKE$, and POKE$$ statements

Purpose Store a byte or sequence of bytes at a specified memory location.

Syntax

```
POKE   [DataType,] Address???, DataValue [, DataValue...]
POKE$  [STRINGZ,]  Address???, StringExpr
POKE$$ [WSTRINGZ,] Address???, StringExpr
```

Remarks The POKE statements and complementary PEEK functions are low-level methods of accessing individual bytes in memory. The data is stored to memory starting at the specified 32-bit address.

In its classic form, the POKE statement stores a single byte (8 bits) whose value ranges from 0 to 255. In its enhanced form, POKE provides the functionality of a dynamic pointer: the *DataType* parameter specifies the data type and hence the size of the target data to write to the target memory address. *DataType* can be any one of BYTE, WORD, DWORD, INTEGER, LONG, QUAD, SINGLE, DOUBLE, EXT, CUR, CUX. If a *DataType* is not specified, BYTE is assumed. If you specify more than one *DataValue*, they are stored in successive memory locations.

POKE$ stores the bytes of *StringExpr* in consecutive bytes of memory. If STRINGZ (or ASCIIZ) is specified, POKE$ writes successive characters to memory, up to the specified size, until a terminating $NUL byte is found in the source string. If no $NUL is found in the string, one is automatically appended. It is the programmer's responsibility to ensure that POKE$ does not overrun the target memory area to avoid data corruption or protection faults.

POKE$$ stores the characters of *StringExpr* as consecutive 2-byte words of memory. If WSTRINGZ is specified, POKE$$ writes successive wide characters, up to the specified size, until a terminating $NUL is found in the source string. If no $NUL is found in the string, one is automatically added. It is the programmer's responsibility to ensure that POKE$$ does not overrun the target memory area to avoid data corruption or protection faults.

Contrarary to intuitive notions, PEEK and POKE execute at the same high performance levels as pointer variables. They offer an excellent alternative to pointers in many situations.

Address??? A valid 32-bit memory address specifying the location in memory where data storage should begin.

Datavalue The data value to be stored at *Address???*.

StringExpr A string constant, literal or expression that specifies the sequence of characters to be stored in memory, starting at by *Address???*.

Restrictions If POKE attempts to access memory that is not allocated to the application, Windows will generate a General Protection Fault (GPF) and terminate the application. GPFs cannot be trapped.

See also GLOBALMEM ALLOC, MEMORY,
, PEEK, STRPTR, VARPTR

POKE$ statement

POKE, POKE$, and POKE$$ statements

Purpose Store a byte or sequence of bytes at a specified memory location.

Syntax

```
POKE   [DataType,] Address???, DataValue [, DataValue...]
POKE$  [STRINGZ,]  Address???, StringExpr
POKE$$ [WSTRINGZ,] Address???, StringExpr
```

Remarks The POKE statements and complementary PEEK functions are low-level methods of accessing individual bytes in memory. The data is stored to memory starting at the specified 32-bit address.

In its classic form, the POKE statement stores a single byte (8 bits) whose value ranges from 0 to 255. In its enhanced form, POKE provides the functionality of a dynamic pointer: the *DataType* parameter specifies the data type and hence the size of the target data to write to the target memory address. *DataType* can be any one of BYTE, WORD, DWORD, INTEGER, LONG, QUAD, SINGLE, DOUBLE, EXT, CUR, CUX. If a *DataType* is not specified, BYTE is assumed. If you specify more than one *DataValue*, they are stored in successive memory locations.

POKE$ stores the bytes of *StringExpr* in consecutive bytes of memory. If STRINGZ (or ASCIIZ) is specified, POKE$ writes successive characters to memory, up to the specified size, until a terminating $NUL byte is found in the source string. If no $NUL is found in the string, one is automatically appended. It is the programmer's responsibility to ensure that POKE$ does not overrun the target memory area to avoid data corruption or protection faults.

POKE$$ stores the characters of *StringExpr* as consecutive 2-byte words of memory. If WSTRINGZ is specified, POKE$$ writes successive wide characters, up to the specified size, until a terminating $NUL is found in the source string. If no $NUL is found in the string, one is automatically added. It is the programmer's responsibility to ensure that POKE$$ does not overrun the target memory area to avoid data corruption or protection faults.

Contrary to intuitive notions, PEEK and POKE execute at the same high performance levels as pointer variables. They offer an excellent alternative to pointers in many situations.

Address??? A valid 32-bit memory address specifying the location in memory where data storage should begin.

Datavalue The data value to be stored at *Address???*.

StringExpr A string constant, literal or expression that specifies the sequence of characters to be stored in memory, starting at by *Address???*.

Restrictions If POKE attempts to access memory that is not allocated to the application, Windows will generate a General Protection Fault (GPF) and terminate the application. GPFs cannot be trapped.

, PEEK, STRPTR, VARPTR

POKE$$ statement

POKE, POKE$, and POKE$$ statements

Purpose Store a byte or sequence of bytes at a specified memory location.

Syntax

```
POKE   [DataType,] Address???, DataValue [, DataValue...]
POKE$  [STRINGZ,]  Address???, StringExpr
POKE$$ [WSTRINGZ,] Address???, StringExpr
```

Remarks The POKE statements and complementary PEEK functions are low-level methods of accessing individual bytes in memory. The data is stored to memory starting at the specified 32-bit address.

In its classic form, the POKE statement stores a single byte (8 bits) whose value ranges from 0 to 255. In its enhanced form, POKE provides the functionality of a dynamic pointer: the *DataType* parameter specifies the data type and hence the size of the target data to write to the target memory address. *DataType* can be any one of BYTE, WORD, DWORD, INTEGER, LONG, QUAD, SINGLE, DOUBLE, EXT, CUR, CUX. If a *DataType* is not specified, BYTE is assumed. If you specify more than one *DataValue*, they are stored in successive memory locations.

POKE$ stores the bytes of *StringExpr* in consecutive bytes of memory. If STRINGZ (or ASCIIZ) is specified, POKE$ writes successive characters to memory, up to the specified size, until a terminating $NUL byte is found in the source string. If no $NUL is found in the string, one is automatically appended. It is the programmer's responsibility to ensure that POKE$ does not overrun the target memory area to avoid data corruption or protection faults.

POKE$$ stores the characters of *StringExpr* as consecutive 2-byte words of memory. If WSTRINGZ is specified, POKE$$ writes successive wide characters, up to the specified size, until a terminating $NUL is found in the source string. If no $NUL is found in the string, one is automatically added. It is the programmer's responsibility to ensure that POKE$$ does not overrun the target memory area to avoid data corruption or protection faults.

Contrarary to intuitive notions, PEEK and POKE execute at the same high performance levels as pointer variables. They offer an excellent alternative to pointers in many situations.

Address??? A valid 32-bit memory address specifying the location in memory where data storage should begin.

Datavalue The data value to be stored at *Address???*.

StringExpr A string constant, literal or expression that specifies the sequence of characters to be stored in memory, starting at by *Address???*.

Restrictions If POKE attempts to access memory that is not allocated to the application, Windows will generate a General Protection Fault (GPF) and terminate the application. GPFs cannot be trapped.

Example

POWERARRAY Object New!

Purpose

The PowerArray object encapsulates the Windows SAFEARRAY structure. Each object contains exactly one SAFEARRAY, and allows you to read, write, and manipulate the elements easily.

The SAFEARRAY is generally considered to be the lowest common denominator of arrays. It's not as fast as a standard PowerBASIC array, but it serves an excellent purpose: It's a "standard" form of array data which can be used to transfer data between programs, modules, and even DLLs created with different versions of the compiler. Other than the possibility of added data types, we do not expect to see the internal format to change in the foreseeable future.

A SAFEARRAY is frequently contained in a VARIANT variable. However, you'll usually find that the array is referenced and identified by a 32-bit pointer to its array descriptor.

Remarks

All array operations are executed with METHOD and PROPERTY invocations on a PowerArray object. When you create or examine a PowerArray, the specific data type is identified by the following VT codes. All of them are predefined in the compiler. VT codes numbered above 200 are unique to PowerBASIC. Other programming languages will not recognize them, giving undefined results.

```
%vt_i2          = 2        %vt_ui4          = 19
%vt_i4          = 3        %vt_i8           = 20
%vt_r4          = 4        %vt_int          = 22
%vt_r8          = 5        %vt_uint         = 23
%vt_cy          = 6        %vt_ptr          = 26
%vt_date        = 7        %vt_userdefined  = 29
%vt_bstr        = 8        %vt_filetime     = 64
%vt_dispatch    = 9        %vt_astr         = 201
%vt_bool        = 11       %vt_stringfix    = 203
%vt_variant     = 12       %vt_wstringfix   = 204
%vt_unknown     = 13       %vt_stringz      = 205
%vt_decimal     = 14       %vt_wstringz     = 206
%vt_i1          = 16       %vt_type         = 211
%vt_ui1         = 17       %vt_ext          = 221
%vt_ui2         = 18       %vt_curx         = 222
```

The array dimensions are stated at the time the array is created by executing the DIM method. The ByRef *Bounds* parameter refers to a PowerBounds UDT which is predefined in the compiler. *Bound* is a PowerBOUND UDT for use with RedimPreserve. It is also predefined in the compiler.

```
TYPE PowerBounds                 TYPE PowerBound
  Elements1 AS LONG                Elements AS LONG
  LowBound1 AS LONG                LowBound AS LONG
  Elements2 AS LONG              END TYPE
  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

**METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>**

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

Example

PowerTime Object New!

Purpose

A PowerTime Object contains a date and time value, allowing easy calculations. The internal representation emulates the Windows FILETIME structure as a quad-integer. This value represents the number of 100-nanosecond intervals since January 1, 1601. A nanosecond is one-billionth of a second.

You create a PowerTime object the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL MyTime AS IPowerTime
LET MyTime = CLASS "PowerTime"
```

Once you have created a PowerTime object, you can manipulate it using the member methods. The IPowerTime interface is DUAL -- member methods may be referenced using either Direct or Dispatch form.

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime, Sign&, Years&, Months&, Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal

***Day&*)**

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

See also DATE$, DAYNAME$, MONTHNAME$, TIME$

PREFIX/END PREFIX statements

Keyword Template

Purpose

Syntax

Remarks

See also

Example

PREFIX/END PREFIX statements New!

Purpose Executes a series of statements, each of which utilizes pre-defined source code.

Syntax

```
PREFIX "source code"
  [additional statements]
END PREFIX
```

Remarks PREFIX/END PREFIX statements enclose a set of statements, each of which has the same specified "*source code*" prepended. The "*source code*" (in languages which support it) is usually required to be the name of an object variable. However, in PowerBASIC, this definition has been expanded greatly to allow virtually any code to be used. This reduces repetitive typing and reduces the risk of typing errors. For example:

PREFIX/END PREFIX	Compiles as:

`PREFIX "MyObject."`
`  Init(xx)`
`  Sleep(2)`
`END PREFIX`
	`MyObject.Init(xx)`
	`MyObject.Sleep(2)`

`PREFIX "MyStruc."`
`  Height = 220`
`  Width  = 345`
`  Color  = %Blue`
 	
`END PREFIX`
	`MyStruc.Height = 220`
	`MyStruc.Width  = 345`
	`MyStruc.Color  = %Blue`

`PREFIX "ASM "`
`  Mov  Eax, Ebx`
`  Mov  Ecx, &H14`
`  IMul Eax, Esi`
`END PREFIX`
	`ASM Mov  Eax, Ebx`
	`ASM Mov  Ecx, &H14`
	`ASM IMul Eax, Esi`

If the "source code" prefix refers to an object variable or a UDT structure variable, be sure it ends with a period (.) to reference members of that item. Otherwise, be sure it contains whole words. Just as with macros and line continuations, you cannot put half a word on one line, and half a word on another. For example, the following code is illegal and will generate an exception:

```
PREFIX "PRI"
  NT #1, "Hello World"
END PREFIX
```

PREFIX/END PREFIX structures may not be nested.

See Also ASM ALIGN

PRINT# statement

PRINT# statement

Purpose Write data to a device or sequential file.

Syntax

```
PRINT # fNum&
PRINT # fNum&, [ExpList] [SPC(n)] [TAB(n)] [,] [;] [...]
PRINT # fNum&, array$()
```

Remarks The first form of the PRINT# statement (with or without a trailing comma) outputs a blank line to the file (i.e. a CR/LF only).

The second form of the PRINT# statement has the following parts, which may occur in any order and quantity, within a single PRINT# statement:

fNum& Number used in an OPEN statement to open a sequential file. It can be any numeric expression that evaluates to the number of an open file. Note that the Number symbol (#) preceding *fNum&* is not optional.

ExpList and/or string expression(s) to be written to the file.

SPC(n) An optional function used to insert *n* spaces into the printed output. Multiple use of the SPC argument is permitted in the PRINT statement, for example, between expressions. Values of *n* less than 1 are ignored.

TAB(n) An optional function used to tab to the *n*th column before printing *ExpList*. Multiple use of the TAB argument is permitted in the PRINT, for example, to position arguments in columns. Values of *n* less than 1 are ignored.

{;|,} Character that determines the position of the next character printed. A semicolon (;) means the next character is printed immediately after the last character; a comma (,) means the next character is printed at the start of the next print zone. Print zones begin every 14 columns.

If the final argument of a PRINT# statement is a semicolon or comma, PRINT# will not append the (default) CR/LF byte pair to the data as it is written to the file. For example:

```
PRINT #1, "Hello";
PRINT #1, " world!"
```

...produces the contiguous string "Hello world!" in the disk file.

If you omit all arguments, the PRINT# statement prints a blank line in the file (i.e., a CR/LF pair only), but you must include the comma after the file number. Because PRINT# writes an image of the data to the file, you must delimit the data so it is printed correctly. If you use commas as delimiters, PRINT# also writes the blanks between print fields to the file. Also, remember that spacing of data displayed on a text screen using monospaced characters may not work well when the data is redisplayed in a graphical environment using proportionally spaced characters.

If you are not careful, you can waste a lot of disk space with unnecessary spaces, or worse, put fields so close together that you cannot tell them apart when they are later input with INPUT#. For example:

```
PRINT #1,1,2,3
```

sends:

```
1             2             3
```

to file #1. Because of the 14-column print zones between characters, superfluous spaces are sent to the file. On the other hand:

```
PRINT #1,1;2;3
```

sends:

```
1 2 3
```

to the file, and you cannot read the separate numeric values from this record because INPUT# requires commas as delimiters. The best way to delimit fields is to put a comma between each field, like so:

```
PRINT #1, 1 "," 2 "," 3
```

which writes:

```
1, 2, 3
```

to the file, and wastes the least possible space and is easy to read with an INPUT# statement. The WRITE# statement delimits fields with commas automatically.

PRINT# is advantageous when writing a single

or on each line in a file. Use PRINT# followed by a comma but no arguments to write a blank line (carriage return/linefeed) to a file:

```
PRINT #1,   'writes a blank line to file #1
```

array$() When PRINT# specifies an array name with empty parentheses, the entire array is written to the disk file as text strings, with each element delimited by a CR/LF ($CRLF or CHR$(13,10)). Numeric arrays are converted to the ASCII text equivalent.

Restrictions Arrays of User-Defined Types (UDTs) may not be used with the array form of the PRINT# statement.

See also GET, GET$, GET$$, INPUT#, LINE INPUT#, PUT, PUT$, PUT$$, WRITE#

Example

```
' Classic PRINT# statement example
SUB MakeFile
  ' opens a sequential file for output. Using PRINT #,
  ' it writes lines of different data types to the file.
  x& = FREEFILE
  OPEN "INPUT#.DTA" FOR OUTPUT AS #x&
  StringVariable$ = "I'll be back."
  IntegerVar% = 1000
  FloatingPoint! = 30000.12
  ' Write a line of text to the sequential file.
  PRINT #x&, StringVariable$
  PRINT #x&, IntegerVar%
  PRINT #x&, FloatingPoint!
  CLOSE #x&  ' close file variable
END SUB ' end procedure MakeFile

SUB ReadFile
  ' Opens a sequential file for input. Using INPUT #,
  ' reads lines of different types of data from the file.
  x& = FREEFILE
  OPEN "INPUT#.DTA" FOR INPUT AS #x&
  RESET StringVariable$
  RESET IntegerVar%
  RESET FloatingPoint!
  ' Read a line of text from the sequential file.

  INPUT #x&, IntegerVar%
  INPUT #x&, FloatingPoint!
  CLOSE #x&  ' close file variable
END SUB ' end procedure ReadFile

' Array mode PRINT# statement example
a$ = "Trevor, Bob, Bruce, Dave, Simon, Jenny"
DIM b$(1 TO PARSECOUNT(a$))
PARSE a$, b$()
ARRAY SORT b$()
```

```
OPEN "filename.txt" FOR OUTPUT AS #1
PRINT #1, b$()
CLOSE #1
```

PRINTER$ function

PRINTER$ function

Purpose Retrieve printer names and printer port names.

Syntax `device$ = PRINTER$([NAME | PORT], printernum&)`

Remarks printernum& specifies the printer number, from 1 to PRINTERCOUNT. If the NAME option is specified in the first position, the printer name is returned. If the PORT option is specified instead, the port name (e.g., LPT1) is returned.

See also LPRINT ATTACH, PRINTERCOUNT, XPRINT ATTACH

PRINTERCOUNT function

PRINTERCOUNT function

Purpose Retrieve the number of available (installed) printers.

Syntax `ncPrinters& = PRINTERCOUNT`

See also LPRINT ATTACH, PRINTER$, XPRINT ATTACH

Example

```
FUNCTION PBMAIN
  LOCAL ix AS LONG, sPrinters AS STRING
  FOR ix = 1 TO PRINTERCOUNT
    sPrinters = sPrinters & PRINTER$(NAME, ix) & $CRLF
  NEXT
  MSGBOX sPrinters
END FUNCTION
```

PROCESS GET PRIORITY statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

PROCESS GET PRIORITY statement

Purpose Retrieve the Priority Value for the current process.

Syntax `PROCESS GET PRIORITY TO lResult&`

Remarks PROCESS GET PRIORITY retrieves the priority value for the current process. The retrieved priority value is assigned to the long or dword variable designated by *lResult&*.

The process priority value is one of the following:

%IDLE_PRIORITY_CLASS = &H00000040

Indicates a process whose
run only when the system is idle and are preempted by the threads of any process running in a higher priority class. An example is a screen saver. The idle priority class is inherited by child processes.

%NORMAL_PRIORITY_CLASS = &H00000020

Indicates a normal process with no special scheduling needs.

%HIGH_PRIORITY_CLASS = &H00000080

Indicates a process that performs time-critical tasks that must be executed immediately for it to run correctly. The threads of a high-priority class process preempt the threads of normal or idle priority class processes. An example is Windows Task List, which must respond quickly when called by the user, regardless of the load on the operating system. Use extreme care when using the high-priority class, because a high-priority class CPU-bound application can use nearly all available cycles.

%REALTIME_PRIORITY_CLASS = &H00000100

Indicates a process that has the highest possible priority. The threads of a real-time priority class process preempt the threads of all other processes, including operating system processes performing important tasks. For example, a real-time process that executes for more than a very brief interval can cause disk caches not to flush or cause the mouse to be unresponsive.

See also PROCESS SET PRIORITY, THREAD GET PRIORITY, THREAD SET PRIORITY

PROCESS SET PRIORITY statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

PROCESS SET PRIORITY statement

Purpose Sets the Priority Value for the current process.

Syntax `PROCESS SET PRIORITY Priority&`

Remarks PROCESS SET PRIORITY assigns a new priority value to the current process.

The process priority value must be one of the following:

%IDLE_PRIORITY_CLASS = &H00000040

Indicates a process whose
run only when the system is idle and are preempted by the threads of any process running in a higher priority class. An example is a screen saver. The idle priority class is inherited by child processes.

%NORMAL_PRIORITY_CLASS = &H00000020

Indicates a normal process with no special scheduling needs.

%HIGH_PRIORITY_CLASS = &H00000080

Indicates a process that performs time-critical tasks that must be executed immediately for it to run correctly. The threads of a high-priority class process preempt the threads of normal or idle priority class processes. An example is Windows Task List, which must respond quickly when called by the user, regardless of the load on the operating system. Use extreme care when using the high-priority class, because a high-priority class CPU-bound application can use nearly all available cycles.

%REALTIME_PRIORITY_CLASS = &H00000100

Indicates a process that has the highest possible priority. The threads of a real-time priority class process preempt the threads of all other processes, including operating system processes performing important tasks. For example, a real-time process that executes for more than a very brief interval can cause disk caches not to flush or cause the mouse to be unresponsive.

See also PROCESS GET PRIORITY, THREAD GET PRIORITY, THREAD SET PRIORITY

PROFILE statement

PROFILE statement

Purpose Capture a profile report detailing total execution times of the Subs , Functions, Methods, and Properties in a program and write it to a disk file.

Syntax `PROFILE diskfilename$`

Remarks At the time the PROFILE statement is executed, a standard sequential file of the specified file name *diskfilename$* is created. For the best results in executable files, the PROFILE statement should be the last statement executed in the PBMAIN/WINMAIN function.

The profile report contains a list of every procedure within the same module (EXE or DLL), the number of times it was called, and the total elapsed time (in milliseconds) spent executing all instances of the procedure. These statistics appear in the disk file in that specific order on each line:

```
<Procedure Name>,  <Call Count>,  <Time mSec>
```

The profile report only describes procedures that physically reside within the module (EXE or DLL) where the PROFILE statement is located. Procedures in an external EXE or DLL are not profiled individually; however, the time taken to call other procedures and DLL/API functions is included in the accumulated execution time of the calling procedure.

It is highly recommended that you close all other applications when profiling a PowerBASIC application. When an application is being profiled, PowerBASIC must generate a considerable amount of extra code to gather all of the needed information. This extra code is generated whenever a valid PROFILE statement appears in your program, regardless of whether it is actually executed.

For final production code, use the #TOOLS OFF metastatement is used to ensure the highest performance levels.

Interpreting a profile report

The execution time of nested procedures needs to be understood in order to obtain a clear "picture" of the execution times. For example, consider the following results:

Procedure	***calls***	***time***
MySubA,	1,	11016
MySubB,	100,	10014

At first glance, these results may suggest a "bottleneck" in *MySubA* since it took *MySubA* 11016 milliseconds to execute just one call, whereas the average time for *MySubB* was only about 100 milliseconds per call (10014 mSec / 100 calls = 100.14 mSec).

However, if *MySubB* is actually **called by** *MySubA*, the results need to be assessed differently. For example, we could say: "*MySubB took 10014 milliseconds of the 11016* *milliseconds of the time spent in MySubA*". Or to put it another way: "*Of the 11016 milliseconds MySubA took to execute, 10014 milliseconds of that time was spent executing MySubB*".

Interpolating these results, it can be easily calculated that the code in *MySubA* only took 1002 milliseconds to run, yet this blossomed to 11016 milliseconds because of its dependence on *MySubB*.

Therefore, improving the performance of *MySubB* would clearly improve the overall speed of *MySubA*, and the profile results of both functions would be improved accordingly.

Restrictions

Profiling is "enabled" when the first procedure that contains a PROFILE statement begins execution. All procedures *subsequently* executed from within that procedure are profiled.

It is not possible to profile the actual PBMAIN or WINMAIN functions. If a PROFILE statement occurs within PBMAIN/WINMAIN, all procedures that are called from PBMAIN/LIBMAIN are profiled normally.

Therefore, if PBMAIN/WINMAIN contains code that requires profiling, simply rename the function and create a new PBMAIN/WINMAIN function that immediately calls the renamed function and then executes a PROFILE statement. See the example below.

For application code with nested and lengthy procedure calls, adding up the total number of milliseconds in the last column of a PROFILE disk file will usually produce a number that is far larger than the actual time it took your program to execute.

The time resolution of the profile report is limited by the *Quantum* supported by the operating system (Win95/98 is 54 mSec, and WinNT/2000/XP is 10 mSec), and can be influenced by any other applications which run concurrently. Nonetheless, PROFILE can offer a great insight as to which code may be consuming the most CPU time, and where optimization efforts should be concentrated.

 PBMAIN,                 1,                      0
```

PROGID$ function

PROGID$ function

Purpose

Return the unique alphanumeric PROGID

(text) associated with a unique CLSID string of a COM object or component. A COM object/component must include an alphanumeric PROGID string in order to be used by PowerBASIC (and Visual Basic).

Syntax

`a$ = PROGID$(ClassID$)`

Remarks

A PROGID string is the unique alphanumeric text name associated with a given COM object/component. For example, "Word.Application.8".

You convert the 16-byte (128-bit) binary class ID of a COM object/component into a PROGID string with the PROGID$ function.

PROGID$ takes the (16-byte) binary string *ClassID$* representing the GUID or UUID of a COM object/component, and examines the system registry in order to determine the PROGID string associated with the *ClassID$* string. ClassID$ may be a dynamic string or fixed-length string of at least 16 bytes, or (typically) a GUID variable.

If the *ClassID$* cannot be found, or any error occurs in the lookup process, PROGID$ will not set the ERR system variable, but will return an empty string.

PROGID$ is the complement to the CLSID$ function. Using these two functions together, it is possible to extract the precise capitalization of the PROGID from the system registry. See the example below.

See also DIM, CLSID$, GUID$, GUIDTXT$, INTERFACE (Direct), INTERFACE (IDBind), ISINTERFACE, ISNOTHING, ISOBJECT, Just what is COM?, LET (with Objects), METHOD, OBJECT, OBJACTIVE, OBJPTR, OBJRESULT, PROPERTY, What is an object, anyway?

Example

```
DIM MSWordClassID AS GUID
MSWordClassID = CLSID$("Word.Application")
IF TRIM$(MSWordClassID, $NUL) <> "" THEN
  'Success getting the CLSID$ of MSWord
  a$ = PROGID$(MSWordClassID)
  'a$ now contains "Word.Application.8"
  b$ = GUIDTXT$(MSWordClassID)
  'b$ holds "{000209FF-0000-0000-C000-000000000046}"
END IF
```

PROGRESSBAR GET POS statement

Keyword Template

Purpose

Syntax

Remarks

Example

PROGRESSBAR statement

Purpose Manipulate a PROGRESSBAR control. A ProgressBar is a rectangle that is gradually filled, left to right, as some work progresses.

Syntax

```
PROGRESSBAR GET POS hDlg, id& TO datav&
PROGRESSBAR GET RANGE hDlg, id& TO LoDatav&, HiDatav&
PROGRESSBAR SET POS hDlg, id&, position&
PROGRESSBAR SET RANGE hDlg, id&, lolimit&, hilimit&
PROGRESSBAR SET STEP hDlg, id&, stepval&
PROGRESSBAR STEP hDlg, id& [,incramt&]
```

hDlg Handle of the dialog that owns the ProgressBar.

id& The control identifier assigned with CONTROL ADD PROGRESSBAR.

Remarks In each of the following samples and descriptions, the PROGRESSBAR control that is the subject of the statement is identified by the handle of the dialog that owns the

ProgressBar (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD PROGRESSBAR. To alter the color of the bar or the background, use CONTROL SET COLOR.

PROGRESSBAR GET POS *hDlg, id&* TO *datav&*

The current position of the ProgressBar is retrieved and assigned to the variable designated by *datav&*.

PROGRESSBAR GET RANGE *hDlg, id&* TO *LoDatav&, HiDatav&*

The current range of the ProgressBar is retrieved and assigned to the variables designated by *LoDatav&* and *HiDatav&*. Upon ProgressBar creation, the default range is 0 to 100.

PROGRESSBAR SET POS *hDlg, id&, position&*

The current position of the ProgressBar is set to the value of the parameter *position&*, and the bar is redrawn to reflect the new position.

PROGRESSBAR SET RANGE *hDlg, id&, lolimit&, hilimit&*

The range for the ProgressBar is specified to be from *lolimit&* to *hilimit&*. If *lolimit&* is greater than *hilimit&*, the results are undefined.

PROGRESSBAR SET STEP *hDlg, id&, step&*

The default increment value to be used by PROGRESSBAR STEP is specified by the *stepval&* parameter.

PROGRESSBAR STEP *hDlg, id&* [*,incramt&*]

The ProgressBar is "stepped". The current position is advanced by the step increment, and the bar is redrawn to reflect the new position. If the optional *incramt&* expression is included, the position is advanced by that amount instead. The default step increment is 10, and the default range is from 0 to 100.

PROPERTY / END PROPERTY statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

PROPERTY/END PROPERTY statements IMPROVED

Purpose Define a PROPERTY procedure within a class.

Syntax

```
[OVERRIDE] PROPERTY GET|SET name [<DispID>] [ALIAS "altname"] (var AS
type...) [THREADSAFE] [AS type]
  [statements]
  PROPERTY = expression
END PROPERTY
```

Remarks PROPERTY/END PROPERTY is used to define a PROPERTY procedure within a class. Properties can only be called through a virtual function table on an active object. A PROPERTY is a special type of METHOD, which is only used to set or retrieve data in an object. While the work of a PROPERTY could readily be accomplished with a standard METHOD, this distinction is convenient to emphasize the concept of encapsulation of instance data within an object. There are two forms of PROPERTY procedures: PROPERTY GET and PROPERTY SET. As implied by the names, the first form is used to retrieve a data value from the object, while the second form is used to assign a value. Properties must be defined within a CLASS Block, and may only be declared within a DECLARE CLASS Block. Properties are defined:

```
PROPERTY GET name [ALIAS "altname"] (BYVAL var AS type...) [THREADSAFE]
AS type
  [statements]
  PROPERTY = expression
END PROPERTY

PROPERTY SET name [ALIAS "altname"] (BYVAL var AS type...) [THREADSAFE]
  [statements]
  variable = value
END PROPERTY
```

When you use PROPERTY SET, the value to be assigned is passed to the right of an equal sign, just like a normal assignment to a variable:

Properties can only be called through a virtual function table on an active object. Property parameters may be of any variable type.

```
ObjVar.Prop1 = NewValue
```

A PROPERTY may be considered "Read-Only" or "Write-Only" by simply omitting one of the two definitions. However, if both GET and SET forms are defined for a particular property, all parameters and the property data type must be identical in both forms, and they must be paired. That is, the PROPERTY SET must immediately follow the PROPERTY GET.

Property parameters may be of any variable type.

You can access a PROPERTY GET with:

```
DIM ObjVar AS MyInterface
LET ObjVar  = NEWCOM Prgid$
1. ObjVar.Prop1(param) TO var
2. CALL ObjVar.Prop1(param) TO var
3. var = ObjVar.Prop1(param)
```

You can access a PROPERTY SET with:

```
DIM ObjVar AS MyInterface
LET ObjVar  = NEWCOM Prgid$
1. ObjVar.Prop1(param) = expr
2. CALL ObjVar.Prop1(param) = expr
```

Note that the choice of Property procedure is syntax directed. In other words, depending upon the way you use the name, PowerBASIC will automatically decide whether the GET or SET PROPERTY should be called.

In every Method and Property, PowerBASIC automatically defines a pseudo-variable named ME, which is treated as a reference to the current object. Using ME, it's possible to call any other Method or Property which is a member of the class: *var* = ME.*Method1*(*param*)

Methods may be declared (using AS *type*...) to return a

, any of the types, a specific class of object variable (AS MyClass), a Variant, or a user defined Type.

Type Libraries only support the following data types: BYTE, WORD, DWORD, INTEGER, LONG, QUAD, SINGLE, DOUBLE, CURRENCY, OBJECT, STRING, and VARIANT. If any Methods or Properties use data types not supported by Type Libraries, you will receive a Error 581 - Type Library creation error, when using the #COM TLIB ON metastatement.

In addition to the explicit return value which you declare, all COM Methods and Properties have another "Hidden Return Value", which is cryptically named hResult. While the name would imply a handle for a result, it's really not a handle at all, but just a long integer value, used to indicate success or failure of the Method. After calling a Method or Property, you can retrieve the hResult value with the PowerBASIC function OBJRESULT. The most significant bit of the value is known as the severity bit. That bit is 0 (value is positive) for success, or 1 (value is negative) for failure. The remaining bits are used to convey error codes and additional status information. If you call any object Method/Property (either Dispatch or Direct), and the severity bit in the returned hResult is set, PowerBASIC generates Run-Time error 99: Object error. When you create a Method or Property, PowerBASIC automatically returns an hResult of zero, which implies success. You can return a non-zero hResult value by executing a METHOD OBJRESULT = *expr* within a Method, or PROPERTY OBJRESULT = *expr* within a Property.

Every method and property in a dual interface needs a positive, long integer value to identify it. That integer value is known as a *DispID* (Dispatch ID), and it's used internally by COM services to call the correct function on a Dispatch interface. You can optionally specify particular *DispID* by enclosing it in angle brackets immediately following the

Method/Property name:

```
METHOD  MethodOne <76> ()
```

If you don't specify a *DispID*, PowerBASIC will assign a random value for you. This is fine for internal objects, but may cause a failure for published COM objects, as the *DispID* could change each time you compile your program. It is particularly important that you specify a *DispID* for each Method/Property in a COM Event Interface.

Override Properties

You can add to, or replace, the functionality of a particular method or property of an inherited base class by coding a replacement which is preceded by the word OVERRIDE. The overriding method must have the same name and signature (parameters, return value, etc.) as the one it replaces.

BYREF and BYVAL parameters

BYVAL	A copy of the data value is placed on the stack as a parameter. The copy is destroyed when the PROPERTY ends. BYVAL parameters default to an IN attribute, if no explicit direction is specified.
BYREF	A pointer to the data is placed on the stack as a parameter. This option may not be used with an internal PROPERTY parameter.

Direction attributes

PROPERTY parameters also specify the direction in which data is passed between the caller and callee:

IN	Data is passed from the caller to the PROPERTY. Generally speaking, you'll find that almost all IN parameters are passed BYVAL, and that is highly recommended. However, it is possible to pass them BYREF if necessary.
OUT	Data is passed from the PROPERTY back to the caller. All OUT parameters must be passed BYREF.
INOUT	Data is passed from the caller to the PROPERTY, and results are returned to the caller in the same parameter. All INOUT parameters must be passed BYREF.

In many cases, the direction of a parameter can be inferred directly from the BYVAL/BYREF attribute (BYVAL=IN, BYREF=OUT). However, we recommend that you include the direction attribute as an added means of self-documentation. Each METHOD parameter name may be preceded by one of BYVAL/BYREF, and one of IN/OUT/INOUT, in any sequence.

You should note an interesting rule of COM objects: **IN parameters are read-only. They may not be altered.**

IN parameters are considered by COM rules to be "constant" which may not be altered, because they are values which are not returned to the caller. However, since this is not a rule normally applied to a standard SUB or FUNCTION, it can allow programming bugs which are most difficult to find and correct. For this reason, PowerBASIC automatically protects you from this issue with no action needed on your part. When writing METHOD or PROPERTY code in PowerBASIC, you may freely assign new values to BYVAL/IN parameters. They will simply be discarded when the METHOD exits. Of course, not every programming language protects you in this way, so you must use caution if you create a COM METHOD in another compiler.

Using OPTIONAL/OPT

PROPERTY statements may specify one or more parameters as optional by preceding the parameter with either the keyword

(or the abbreviation OPT). When a parameter is declared optional, all subsequent parameters in the declaration are optional as well, whether or not they specify an explicit OPTIONAL or OPT directive.

VARIANT variables are particularly well suited for use as an optional parameter. If the calling code omits an optional VARIANT parameter, (BYVAL or BYREF), PowerBASIC (and most other compilers) substitute a variant of type %VT_ERROR which contains an error value of %DISP_E_PARAMNOTFOUND (&H80020004). In this case, you can check for this value directly, or use the ISMISSING function to determine whether the parameter was physically passed or not.

When optional parameters (other than VARIANT) are omitted from the calling code, the stack area normally reserved for those parameters is zero-filled.

If the parameter is defined as a BYVAL parameter, it will have the value zero. For TYPE or UNION variables passed BYVAL, the compiler will pass a string of binary zeroes of length SIZEOF(*Type_or_union_var*).

If the parameter is defined as a BYREF parameter, VARPTR(*Varname*) will equal zero; when this is true, any attempt to use *Varname* in your code will result in a General Protection Fault or memory corruption. You should use the ISMISSING() function first to determine whether it is safe to access the parameter.

THREADSAFE Option Descriptor

If you include the option THREADSAFE, PowerBASIC automatically establishes a semaphore which allows only one

to execute it at a time. Others must wait until the first thread exits the THREADSAFE procedure before they are allowed to begin.

Example

```
CLASS cMyClass
  INSTANCE Value AS LONG

  INTERFACE iMyClass
    INHERIT IDISPATCH

    PROPERTY GET Value <1> AS LONG
      PROPERTY = Value
    END PROPERTY

    PROPERTY SET Value <1> (BYVAL NewValue AS LONG)
      Value = NewValue
    END PROPERTY

  END INTERFACE
END CLASS
```

PUT statement

PUT statement

Purpose Write a record to a random-access file or a variable/array to a binary file.

Syntax

```
Random-Access and Binary files:
PUT [#] FileNum&, [RecPos], [ABS] Var
PUT [#] FileNum& [, RecPos]
Binary files:
PUT [#] FileNum&, [RecPos], Arr()
```

Remarks If a

	variable is specified as *Var*, the CHR mode of the variable determines whether the data is written as ANSI or WIDE characters. That is, ANSI string variables are always written as 1-byte characters, while WIDE string variables are written as 2-byte WIDE characters. The data is always written to the file in the same format as it appears in the variable.
FileNum&	The file number under which the file was opened.
RecPos	Identifies the position in the file to write the data. If *RecPos* is greater than the number of existing records or bytes in the file, the file is extended to the appropriate length, and the record is written at the specified position. **For random access files,** *RecPos* is the record to be written, in the range 1 to (2^63)-1. If *RecPos* is omitted, the next record in sequence (following the one specified by the most recent GET, PUT or SEEK) is written. If the file was only just opened, the first record is written. **For binary files**, *RecPos* is the starting byte position where *VarName* should be written. The default byte position is 1, unless the BASE = 0 clause was used in the OPEN statement. *RecPos* may be no larger than 2^63-1. *RecPos* is optional. If it is omitted, PowerBASIC uses the current file pointer position.

Var	The name of a variable to write to the file. *VarName* can specify a simple variable, an element in an array, or a variable of User-Defined Type (UDT).
	
	When writing a dynamic string to a random access file, PUT writes a 2-byte descriptor containing the string's length, before the actual string data. This descriptor reduces the available space in a record by two bytes. The descriptor is written as a WORD value. If *Var* contains more characters than record, *Var* is truncated at record length less two bytes, and the descriptor is written to reflect the truncated string size.
	
	When writing a dynamic string to a binary file, PUT only writes the actual string data: no length descriptor is written.
	
	PUT is complementary to GET; it writes one record to a file. It is possible to PUT to records out of contiguous order, as in:
	
	`PUT #1, 1, MyVar`
	`PUT #1, 100, MyVar`
	
	which creates a random-access file 100 records long. The data in records 2 through 99, however, are undefined until you explicitly PUT something there. PUT writes the contents of *Var* to the specified record or byte positions.

(no *VarName*)	When the second form of PUT is used (without a *VarName* source string), PUT writes the data from an internal buffer into the file at the point where the file pointer indicates. This data must first be assigned to the file buffer using FIELD string variables.
ABS	When PUT is used to write a dynamic string to a random file, it normally precedes the actual data with a two-byte binary length Word to define the number of valid bytes in the record. If you precede the variable name with ABS (i.e., PUT #1, , ABS x$), no length Word is written: only the actual data, subject to the defined random record length. This offers greater compatibility with the actual operation of other versions of BASIC, such as PowerBASIC for DOS. **The record length in a random access file is limited to 32768 bytes, in order to ensure consistent behavior across all Win32 platforms.**
Arr()	When PUT is used on a binary file, the entire array specified by *Arr()* is written to the file. With dynamic strings, the file is written in the PowerBASIC and/or VB packed string format. If the string is shorter than 65535 bytes, a 2-byte length Word is followed by the string data. Otherwise, a 2-byte value of 65535 is followed by a length Double-word (DWORD), then finally the string data. With other data types, the entire data area is written as a single block.In either case, it is presumed the file will be read with the complementary GET Array statement.

TYPE, WRITE#

Example

```
' Random-access PUT example
TYPE TestRec
  uName   AS STRING * 10
  uNumber AS INTEGER
END TYPE

DIM Rec AS TestRec, Record AS QUAD

OPEN "RANDOM.DTA" FOR RANDOM AS #1 LEN = LEN(TestRec)

FOR Record = 1 TO 100
  Rec.uName = "Joe" + STR$(Record)
  Rec.uNumber = Record
  PUT #1,Record, Rec
NEXT Record

CLOSE #1

' Binary PUT Array example
DIM TheData$(1 TO count&)
TheData$(1) = "text"
' Assign more array values...
OPEN "Data file to write.dat" FOR BINARY AS #1
PUT #1, 1, TheData$()
CLOSE #1
```

PUT$ statement

PUT$ statement IMPROVED

Purpose Writes an ANSI

to a file opened in binary mode.

Syntax **PUT$ [#] *filenum&, StrgExpr***

Remarks PUT$ first evaluates the string expression. If it results in a WIDE Unicode string, it is converted to ANSI byte characters. PUT$ then writes the ANSI string to the file specified by *FileNum&* at the current file pointer position. GET$, PUT$, and SEEK provide a low-level alternative to sequential and random-access file processing techniques, allowing you to deal with files on a byte by byte basis.

File *filenum&* must have been opened in binary mode. Bytes are written starting at the current file pointer position, which can be set with the SEEK statement. When the file is first opened, the pointer is at the beginning of the file (position 1, by default, unless BASE=0 was specified in the OPEN statement). After PUT$, the file pointer position is automatically advanced to the point which immediately follows the just written data. You can use

to retrieve or change the file pointer position.

Filenum& The file number under which the file was opened.

StrgExpr A string expression which is written to the file.

See also GET, GET$, GET$$, OPEN, PUT, PUT$$, SEEK function, SEEK statement, SETEOF, WRITE#

Example

```
' Open a binary file and write the alphabet to it
OPEN "SEEK.DTA" FOR BINARY AS #1 BASE = 1
FOR I& = ASC("A") TO ASC("Z")   ' 65 TO 90
  PUT$ #1, CHR$(I&)
```

```
NEXT
CLOSE #1
```

PUT$$ statement

Example

PUT$$ statement New!

Purpose Writes a WIDE Unicode

to a file opened in binary mode.

Syntax **PUT$$ [#] *filenum&, StrgExpr***

Remarks PUT$$ first evaluates the string expression. If it results in an ANSI string, it is converted to WIDE Unicode characters. PUT$$ then writes the WIDE string to the file specified by *FileNum&* at the current file pointer position. GET$$ and PUT$$ provide a low-level alternative to sequential and random-access file processing techniques, allowing you to deal with files on a character by character basis.

File *filenum&* must have been opened in binary mode. Characters are written starting at the current file pointer position, which can be set with the SEEK statement. When the file is first opened, the pointer is at the beginning of the file (position 1, by default, unless BASE=0 was specified in the OPEN statement). After PUT$$, the file pointer position is automatically advanced to the point which immediately follows the just written data. You can use

to retrieve or change the file pointer position.

Filenum& The file number under which the file was opened.

StrgExpr A string expression which is written to the file.

See also GET, GET$, GET$$, OPEN, PUT, PUT$, SEEK function, SEEK statement, SETEOF, WRITE#

RAISEEVENT statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

RAISEEVENT statement

Purpose Call Event Handler code.

Syntax `RAISEEVENT ObjVar.Method()`

Remarks The RAISEEVENT statement is used to call event handler code from an Event Source. RAISEEVENT may only appear within a class which declares the Event Source interface. The concept of RAISEEVENT is very similar to the CALL statement, but it may only be used to execute event procedures:

```
RaiseEvent Status.Progress(10) ' advise the code is 10% done
```

It should be noted that RAISEEVENT does not reference an object variable at all, because it calls any and all Direct, V-Table event handlers which are currently subscribed to these events. Instead, it references the interface name (in this case "Status"), followed by the name of the Event Method to be executed (in this case "Progress"). If your program is using a Dispatch event handler you should use the OBJECT RAISEEVENT statement instead.

See also CLASS, EVENT SOURCE. EVENTS, INTERFACE (Direct), INTERFACE (IDBind), Just what is COM?, EVENTS, OBJECT RAISEEVENT, What is an object, anyway?, What are Connection Points?

Example See the EVENT SOURCE statement for an example of RAISEEVENT.

RANDOMIZE statement

RANDOMIZE statement

Purpose Seed the random number generator.

Syntax `RANDOMIZE [number]`

Remarks *number* is a seed value that may be any

type. If *number* is not specified, the value returned by the TIMER function is used.

Values returned by the random number generator (RND) depend on an initial seed value. For a given seed value, RND always returns the same sequence of values, yielding a predictable pseudo-random number sequence. Thus, any program that depends on RND will run exactly the same way each time unless a different seed is given.

The default seed can be duplicated with the following statement:

```
RANDOMIZE CVS(CHR$(255,255,255,255))
```

Note that each thread has its own, independent random number seed.

See also RND, TIMER

Example

```
' Seed generator and get 5 random values
RANDOMIZE 1.5!
FOR I& = 1 TO 5
  Table(I&) = RND(1,100)
NEXT I&

' Reseeding with the same starting value
' means you get the same sequence of values!
RANDOMIZE 1.5!
FOR I& = 1 TO 5
  Table(I&) = RND(1,100)
NEXT I&

' Now reseed from the TIMER and we get
' a completely different set of values:
RANDOMIZE TIMER
FOR I& = 1 TO 5
  Table(I&) = RND(1,100)
NEXT I&
```

READ$ function

READ$ function

Purpose Retrieve data from a local DATA list.

Syntax ***value$*** **= READ$(*n%*)**

Remarks The READ$ function is used to retrieve a specified string data item from a local DATA list, and returns the data in string format. READ$ offers a simple technique for random-access of local DATA.

n% An expression, constant, or variable, which specifies an index position in the local DATA list. *n%* = 1 for the first data item, *n%* = 2 for the second, and so on. READ$ accesses the DATA statements in the order in which they appear in the source program, from left to right.

If *n%* is greater than DATACOUNT, READ$ returns an empty string, but no run-time error occurs.

*value$* READ$ places the DATA string into *value$.*

If the target DATA statement is enclosed in quotes, READ$ preserves any leading or trailing spaces that it may contain; otherwise, READ$ trims leading and trailing spaces and returns a trimmed string. See DATA for more information on data item formatting.

If numeric data needs to be stored in DATA statements and retrieved with READ$, the VAL function can be used to convert the return values from READ$ into numeric values.

Restrictions There is a limit of 64 Kilobytes and 16384 separate data items per Sub, Function, Method, or Property, and it is not possible to read DATA from outside of the scope of current procedure. Restrictions apply to using colon and underscore characters in DATA statements - see DATA for more information.

See also DATA, DATACOUNT

Example

```
' The following returns the day of the week string.
FUNCTION WeekDayName$(BYVAL DayNum%)
  IF DayNum% < 1 OR DayNum% > DATACOUNT THEN
    WeekDayName$ = ""
  ELSE
    WeekDayName$ = READ$(DayNum%)
  END IF
  DATA Sun, Mon, Tue, Wed, Thu, Fri, Sat
END FUNCTION
```

REDIM statement

REDIM statement

Purpose Used at the to declare dynamic array variables and allocate, deallocate, or reallocate storage space.

Syntax **REDIM [PRESERVE] *array*([*subscripts*]) [AS *type*] [AT *address*] [, ...]**

Remarks The REDIM statement allows dynamic arrays (including string arrays) to be erased and re-dimensioned. It is really just a shortcut for the two-step process ERASE *x*(), followed by DIM *x*(). REDIM uses the same basic syntax as the DIM statement.

array is the name of the array, and *subscripts* is either a group of single integers (one per dimension of a particular array), or a group of ranges (REDIM arr1(5 TO 25, 1 TO 4, 3 TO 8)), separated by commas.

AS *type* — The AS *type* clause is optional, but recommended for the purposes of clarity.

AT *address* — The AT *address* clause indicates the array is to be an absolute array. Absolute arrays are not reset by the REDIM statement, nor are they reset when the Sub/Function/Method/Property exits, but they can be reset with the RESET statement. See the discussion in the DIM topic for more information on absolute arrays.

PRESERVE — The PRESERVE keyword tells the compiler to preserve the values of all existing elements in the array. For example, if you REDIM PRESERVE an array with 10 elements to 20 elements, the first 10 elements will retain their original value. The remaining 10 elements will be initialized to zero (or null/empty in the case of a string array). If the array is resized to be smaller, the specified number of elements is preserved, and the remaining elements are discarded. **When PRESERVE is specified, you can resize only the upper boundary of the last (outer) dimension of the array**. Arrays of only one dimension can always be resized.

In a procedure, you can use REDIM to re-dimension an array that was passed as an argument. That is, when the complete array was passed to the procedure:

```
CALL RemoveDuplicates( CustomerNames$() )
' more code here
SUB RemoveDuplicates( a$() )
  ' Remove duplicate array values
  REDIM PRESERVE a$(1 TO NewCount&)
END SUB
```

REDIM may also be used to alter the size of Static, Global, and Instance arrays.

When used with no subscript parameters, REDIM will erase all contents of an array and deallocate the memory used:

```
REDIM xyz&()  ' Equivalent to ERASE xyz&()
```

Restrictions — **When PRESERVE is specified, *only the upper bound of the last (outer) dimension may be redefined.***

When a REDIM statement is executed, the location of the array elements always moves in memory; however, the array's *Descriptor* location (VARPTR(*arrayname*()) will remain fixed at the original location. When using REDIM, your code must be sure to refresh any pointers that target the array data memory locations (STRPTR(*arrayname*(*subscript*)) for dynamic string arrays, and VARPTR(*arrayname*(*subscript*)) for all other array types).

While PowerBASIC supports lower boundary values that are non-zero, PowerBASIC generates the most efficient code if the lower boundary parameter is omitted (i.e., the array uses the default lower boundary of zero).

See also — ARRAYATTR, DIM, ERASE, RESET

Example

```
DIM MyData(40), Names$(100)
REDIM MyData(5 TO 50), Names$(10)
```

REGEXPR statement

REGEXPR statement

Purpose — Scan a

for a matching "wildcard" or regular expression.

Syntax — **REGEXPR *mask$* IN *target$* [AT *start&*] TO *iPos&* [, *iLen&*]**

Remarks — REGEXPR scans *target$* for a matching expression specified in *mask$*. If found, it returns the position of the match in the *iPos&* variable (indexed to the first character position), and optionally, the length of the matching expression in *iLen&*.

If a match is made, the *iPos&* and *iLen&* results can be immediately used with subsequent string operations such as MID$ to extract the matched portion of *target$*, and/or to continue the search through the remainder of *target$*. If no matching expression is found, both *iPos&* (and *iLen&* if specified) are set to zero.

If specified, the search begins at the character position *target&* in *target*$; however, *start&* must be between 1 and the length of *target$*. If *start&* is less than 1, the *start&* parameter is ignored.

While it is possible for more than one match to be found in a particular target string, REGEXPR first selects one or more matches which start at the leftmost possible position, then returns the longest of those. Use the \s special escape operator to force a match on the shortest match (see below).

The ^ and $ operators match on both the actual string start/end, or the previous/next embedded line-delimiter characters (CHR$(13,10) or $CRLF) in *target$*. This enables REGEXPR to treat the *target$* string as containing a set of "logical lines" of text. In this situation, the *start&* character position plays a crucial role in identifying which logical delimited line that should be examined by REGEXPR.

By default, search expressions are assumed to be case-insensitive, so capitalization is ignored.

mask$* The regular (*wildcard*) expression specified in *mask$ may contain a combination of standard text characters and/or the *metacharacters* which are defined as follows:

Char	Definition
.	**(period)** Matches any character, *except* the end-of-line.
^	(caret) Matches the actual beginning-of-line position or the preceding line-delimiter character pair (CHR$(13,10) or $CRLF), as taken from the *start&* character position. The line-delimiter characters themselves are not included in the *iLen&* result. (also see [^] below for usage within a character class definition).
$	**(dollar)** Matches the end-of-line position, which may be either the first line-delimiter character pair (CHR$(13,10) or $CRLF) that is encountered in the search to the right of the *start&* position, or the actual end of the *target*$ string, whichever occurs first. The line-delimiter characters themselves are not included in the *iLen&* result.
|	**(stile)** Specifies alternation (the OR operator), so that an expression on either side can match. Precedence is from left-to-right, as encountered in the expression.
?	**(question mark)** Specifies that zero or one match of the preceding sub-pattern is allowed. Cannot be used with a Tag.
+	**(plus)** Specifies that one or more matches of the preceding sub-pattern are allowed. Cannot be used with a Tag.
*	(asterisk) Specifies that zero or more matches of the preceding sub-pattern are allowed. Cannot be used with a Tag.

Character classes

[ ] **(square brackets)** Identifies a user-defined class of characters, any of which will match: [abc] will match a, b, or c. Only three special metacharacters are recognized within a class definition, the caret ^ for complemented characters, the hyphen - for a range of characters, or one of the following \ backslash escape sequences:

\\ \- \] \e \f \n \q \r \t \v \x##

Any other use of a backslash within a class definition yields an undefined operation that should be avoided.

[-] **(hyphen)** The hyphen identifies a range of characters to match. For example, [a-f] will match a, b, c, d, e, or f.

Characters in an individual range must occur in the natural order as they appear in the character set. For example, [f-a] will match nothing.

Lists of characters, and one or more ranges of characters, may be intermixed in a single class definition. The start and end of a range may be specified by a literal character, or one of the \ backslash escape sequences:

\\ \- \] \e \f \n \q \r \t \v \x##

Any other use of a backslash within a class definition yields an undefined operation.

Multiple ranges in a class are valid. For example, [a-d2-5] matches a, b, c, d, 2, 3, 4, or 5.

When the hyphen is escaped, it is treated as a literal. For example, [a\-c] is a list, not a range, and matches a, -, or c due to the \ backslash escape sequence.

[^] **(caret)** When the caret appears as the first item in a class definition, it identifies a complemented class of characters, which will not match. For example, [^abc] matches any character *except* a, b, or c.

A range can also be specified for the complemented class. For example, [^a-z] matches any character except a through z.

A caret located in any position other than the first is treated as a literal character.

Tags/sub-patterns

( ) **(parentheses)** Parentheses are used to match a Tag, or sub-pattern, within the full search pattern, and remember the match. The matched sub-pattern can be retrieved later in the mask (or in a replace operation with REGREPL), with \01 through \99, based upon the left-to-right position of the opening parentheses.

Parentheses may also be used to force precedence of evaluation with the alternation operator. For example, "(Begin)|(End)File" would match either "BeginFile" or "EndFile", but without the Tag designations, "Begin|EndFile" would only match either "BeginndFile" or "BegiEndFile".

Escaped characters

\ **(backslash)**. The escape operator (single-character quote). The following character will be treated as a literal value rather than being interpreted as a special character. Note that the character following the backslash must actually be a special character, as follows:

\b **A word boundary**. The start or end of a word, where a word is defined as one or more characters that include an alphabetic character (A-Z or a-z), a numeric character (0-9), and an underscore. For example, "abc_123" is considered a single word and "abc-123" is considered two words.

\c **Case-sensitive search**. Without the \c operator, the default is to ignore case when matching. Unlike some other implementations of regular expressions, case-insensitivity is recognized in all operations, even a range of characters such as "[6-Z]". The \c operator may appear at any position in the mask.

\e **Escape character**: CHR$(27) or $ESC.

\f **Formfeed character:** CHR$(12) or $FF.

\n **Linefeed (or new-line) character:** CHR$(10) or $LF.

\q **Double-quote mark ("):** CHR$(34) or $DQ. \q is included for ease of inclusion within a literal string. For example: "\qHello\q".

\r **Carriage-return character:** CHR$(13) or $CR.

\s	**Shortest match character:** The \s flag causes the shortest matching string to be returned, rather than the longest (the default). For example, when searching for the mask "abc.*abc" in "abcdabcabc", the default setting would return position 1 and length 10. With the \s switch set, it returns position 1 and length 7. This option may cause a slight increase in processing time. The \s flag must appear at the beginning of the mask string.
\t	**Horizontal tab character:** CHR$(9) or $TAB.
\v	**Vertical tab character:** CHR$(11) or $VT.
\x##	**Hex character code:** Indicates that an ASCII code follows, given by two hexadecimal digits. For example, \xFF = CHR$(&HFF) (which is equivalent to CHR$(255)). XX must be in the range 0 through 255.

Restrictions To maximize performance, avoid overuse of the *, + and ? metacharacters.

See also REGREPL, Online Regular Expression Tester

Example

```
a$ = "please send email to support@powerbasic.com"
b$ = "([a-z0-9._/+-]+)(@[a-z0-9.-]+)"
REGEXPR b$ IN a$ TO position&, length&
email_address$ = MID$(a$, position&, length&)

a$ = "Amount owed: $42.75 and is overdue!"
b$ = "\$[0-9.,]+"
REGEXPR b$ IN a$ TO position&, length&
amount$ = MID$(a$, position&, length&)

a$ = "Open 24 Hours"
b$ = "[^a-z ]+"
REGEXPR b$ IN a$ TO position&, length&
hours$ = MID$(a$, position&, length&)

a$ = "Line 1" + $CRLF + "Line 2" + $CRLF
b$ = "([0-9])$"
RESET position& : RESET length&
DO
  position& = position& + length&
  REGEXPR b$ IN a$ AT position& TO _
      position&, length&
  c$ = "Match at " + STR$(position&)
LOOP WHILE position&
```

REGISTER statement

REGISTER statement

Purpose To define Register variables, which are local to a Sub, Function, Method, or Property. The REGISTER statement provides an optimization hint to the compiler.

Syntax `REGISTER variable [AS type] [, variable [AS type]]`

Remarks The REGISTER statement is used to define certain local variables as Register variables - that is, variables which are stored directly in specific CPU registers, rather than in application memory. Since data in a CPU register can be accessed much faster, and with less code, Register variables are valuable optimization tools.

Register variables are always local to the procedure where they appear. In the current version of PowerBASIC, there may be up to two integral-class variables (Word/Dword/Integer/Long) and up to four Extended-precision floats. It is possible that future versions of the compiler will change these limits, so you may declare an unlimited number of them. Any "extra" Register variables are automatically reclassified as locals during compilation.

The REGISTER statement allows you to choose which variables will be classified as Register variables. If you do not make the choice in a particular procedure, the compiler will attempt to choose for you. By default, the compiler will always assign any integral-class local variables available. Extended-precision float variables will be automatically assigned only in Functions that contain no external Function calls.

Integral class Register variables are most efficient for variables that are updated or used often, such as For/Next loop counter variables, and variables that are used repeatedly as array indexes.

Floating-point Register variables should generally be chosen with a bit more caution, since the compiler must generate code to save and restore them to conventional memory around each call to a procedure. In some rather rare cases, it is possible that floating-point Register variables could actually reduce execution speed. However, they are extremely valuable with intensive floating-point calculations in Functions that have few references to other procedures.

Due to the design of FPUs (floating point units), and the instruction sets available, the first float register variable declared in your program has far more optimization possibilities than the others do. Use care in choosing the variable which is used most within floating-point expressions (that is, on the right side of the '=' assignment operator), in order to gain the greatest advantage in execution speed. Also, remember it is typically valuable to assign floating-point constants to Register variables when they are used in repetitive or intensive calculations.

You must use care with Inline Assembler floating-point opcodes in Functions that enable Register variables. Floating-point Register variables may occupy up to four of the FPU registers, so you must limit your use of the x87 registers to the remaining four. Further, floating-point Register variables may never be referenced by name from Inline Assembler code, as the compiler cannot always track the register locations with absolute certainty.

Restrictions

VARPTR cannot be used on a Register variable.

PowerBASIC transparently prevents the *automatic* register conversion of the variable used in the TO clause of the DIALOG SHOW MODAL and DIALOG SHOW MODELESS statements. If the target variable is *explicitly* declared as a register variable, PowerBASIC raises a compile-time Error 491 ("Invalid register variable"). This is necessary as the result values stored in such variables may be assigned from the context of other procedures, and this may only occur with a memory variable.

#REGISTER, Optimizing your code

Example

```
SUB ReindexDatabase() AS LONG
  #REGISTER NONE    ' I'll choose my own register vars.
  REGISTER i AS LONG
  REGISTER fVar AS EXT
  ' do something
END FUNCTION
```

REGREPL statement

REGREPL statement

Purpose

Scan a

for a matching "wildcard" or regular expression, and replace it with a new value.

Syntax

REGREPL *mask$* IN *target$* WITH *repl$* [AT *start&*] TO *iPos&*, *newtarget$*

Remarks

REGREPL scans *target$* for a matching regular expression specified in *mask$*. If a match is made, REGREPL replaces the matched text with the contents of *repl$*, and assigns the new text to *newtarget$*. Additionally, REGREPL sets *iPos&* to reflect the character position immediately following the matched text in *newtarget$*, so the operation can be repeated, if desired.

If no matching expression is found, *iPos&* will be set to zero, and *newtarget$* receives a direct copy of *target$*. In either case, *target$* remains unchanged.

mask$ may contain literal characters and *metacharacters* (wildcards) to form the regular expression, and *repl$* may only contain literal characters and tags specified by \##. Each tag from \01 through \99 is replaced by the text actually matched for that tag. \00 is replaced by the entire matched text.

If specified, the search begins at the character position *start&* in *target$*; however, *start&* must be between 1 and the length of *target$*. If *start&* is less than 1, the *start&* parameter is ignored.

While it is possible for more than one match to be found in a particular target string, REGREPL first selects one or more matches which start at the leftmost possible position, then returns the longest of those. Use the \s special escape operator to force a match on the shortest match (see below).

The ^ and $ operators match on both the actual string start/end, or the previous/next embedded line-delimiter characters (CHR$(13,10) or $CRLF) in *target$*. This enables REGREPL to treat the *target$* string as containing a set of "logical lines" of text. In this situation, the *start&* character position plays a crucial role in identifying which logical delimited line that should be examined by REGREPL.

By default, search expressions are assumed to be case-insensitive, so capitalization is ignored.

mask$* The regular (*wildcard*) expression specified in *mask$ may contain a combination of standard text characters and/or the *metacharacters* which are defined as follows:

Char	Definition
.	**(period)** Matches any character, *except* the end-of-line.
^	**(caret)** Matches the actual beginning-of-line position or the preceding line-delimiter character pair (CHR$(13,10) or $CRLF), as taken from the *start&* character position. The line-delimiter characters themselves are not replaced by *repl$*. (also see [^] below for usage within a character class definition).
$	**(dollar)** Matches the end-of-line position, which may be the either the first line-delimiter character pair (CHR$(13,10) or $CRLF) that is encountered in the search to the right of the *start&* position, or the actual end of the *target$* string, whichever occurs first. The line-delimiter characters themselves are not replaced by *repl$*.
|	**(stile)** Specifies alternation (the OR operator), so that an expression on either side can match. Precedence is from left-to-right, as encountered in the expression.
?	**(question mark)** Specifies that zero or one match of the preceding sub-pattern is allowed. Cannot be used with a Tag.
+	**(plus)** Specifies that one or more matches of the preceding sub-pattern are allowed. Cannot be used with a Tag.
*	**(asterisk)** Specifies that zero or more matches of the preceding sub-pattern are allowed. Cannot be used with a Tag.
Character classes	
[ ]	**(square brackets)** Identifies a user-defined

class of characters, any of which will match: [abc] will match a, b, or c. Only three special metacharacters are recognized within a class definition, the caret (^) for complemented characters, the hyphen (-) for a range of characters, or one of the following \ backslash escape sequences:

\\ \- \] \e \f \n \q \r \t \v \x##

Any other use of a backslash within a class definition yields an undefined operation that should be avoided.

[-]	**(hyphen)** The hyphen identifies a range of characters to match. For example, [a-f] will match a, b, c, d, e, or f. Characters in an individual range must occur in the natural order as they appear in the character set. For example, [f-a] will match nothing. Lists of characters, and one or more ranges of characters, may be intermixed in a single class definition. The start and end of a range may be specified by a literal character, or one of the \ backslash escape sequences: \\ \- \] \e \f \n \q \r \t \v \x## Any other use of a backslash within a class definition yields an undefined operation. Multiple ranges in a class are valid. For example, [a-d2-5] matches a, b, c, d, 2, 3, 4, or 5. When the hyphen is escaped, it is treated as a literal. For example, [a\-c] is a list, not a range, and matches a, -, or c due to the \ backslash escape sequence.
[^]	**(caret)** When the caret appears as the first item in a class definition, it identifies a complemented class of characters, which will not match. For example, [^abc] matches any character *except* a, b, or c. A range can also be specified for the complemented class. For example, [^a-z] matches any character except a through z. A caret located in any position other than the first is treated as a literal character.

Tags/sub-patterns

( )	**(parentheses)** Parentheses are used to match a Tag, or sub-pattern, within the full search pattern, and remember the match. The matched sub-pattern can be retrieved later in the mask, or in a replace operation, with \01 through \99, based upon the left-to-right position of the opening parentheses. Parentheses may also be used to force precedence of evaluation with the alternation operator. For example, "(Begin)|(End)File" would match either "BeginFile" or "EndFile", but without the

	Tag designations, "Begin|EndFile" would only match either "BeginndFile" or "BegiEndFile". Note: Parentheses may not be used with ? + * as any match repetition could cause the tag value to be ambiguous. To match repeated expressions, use parentheses followed by \01*.

Escaped characters

\	(backslash). The escape operator (single-character quote). The following character will be treated as a literal value rather than being interpreted as a special character. Note that the character following the backslash must actually be a special character, as follows:
\b	**A word boundary**. The start or end of a word, where a word is defined as one or more characters that include an alphabetic character (A-Z or a-z), a numeric character (0-9), and an underscore. For example, "abc_123" is considered a single word and "abc-123" is considered two words.
\c	**Case-sensitive search**. Without the \c operator, the default is to ignore case when matching. Unlike some other implementations of regular expressions, case-insensitivity is recognized in all operations, even a range of characters such as "[6-Z]". The \c operator may appear at any position in the mask.
\e	**Escape character:** CHR$(27) or $ESC.
\f	**Formfeed character:** CHR$(12) or $FF.
\n	**Linefeed (or newline) character:** CHR$(10) or $LF.
\q	**Double-quote mark ("):** CHR$(34) or $DQ. \q is included for ease of inclusion within a literal string. For example: "\qHello\q".
\r	**Carriage-return character:** CHR$(13) or $CR.
\s	**Shortest match character:** The \s flag causes the shortest matching string to be returned, rather than the longest (the default). For example, when searching for the mask "abc.*abc" in "abcdabcabc", the default setting would return position 1 and length 10. With the \s switch set, it returns position 1 and length 7. This option may cause a slight increase in processing time. The \S flag must appear at the beginning of the mask string.
\t	**Horizontal tab character:** CHR$(9) or $TAB.
\v	**Vertical tab character:** CHR$(11) or $VT.
\x##	**Hex character code:** Indicates that an ASCII code follows, given by two hexadecimal digits. For example, \xFF = CHR$(&HFF) (which is equivalent to

	CHR$(255)). XX must be in the range 0 through 255.
\##	**Tag number:** Evaluated as the characters matched by tag number ## (where ## is in the range 01 through 99, in decimal). Tags are implicitly numbered from 01 through 99, based upon the left-to-right position of the left parenthesis. "(…)w\01" would match "abcwabc" or "456w456".

Tags cannot be forward-referenced - that is, if a reference is made to any Tag that is not yet defined, a non-match is presumed.

Restrictions To maximize performance, avoid overuse of the *, + and ? metacharacters.

See also REGEXPR

Example

```
#COMPILE EXE
FUNCTION PBMAIN
  a$ = "please email support@powerbasic.com"
  b$ = "([a-z0-9._/+-]+)(@[a-z0-9.-]+)"
  c$ = "sales\02"
  REGREPL b$ IN a$ WITH c$ TO position&, d$
  ' d$ -> "please email sales@powerbasic.com"

  a$ = "Line 1" + $CRLF + "Line 2" + $CRLF
  b$ = "([0-9])$"
  c$ = "\01.0"
  position& = 1
  DO
    REGREPL b$ IN a$ WITH c$ AT position& TO position&, a$
  LOOP WHILE position&
  ' a$ -> " Line 1.0" + $CRLF + "Line 2.0" + $CRLF
END FUNCTION
```

REM statement

REM statement

Purpose Indicate that the remainder of a line in source code files is to be regarded as a Remark or Comment, and excluded from the compiled code.

Syntax

```
REM comment text
' comment text
; comment in an Inline Assembler statement
```

Remarks The PowerBASIC compiler ignores Remarks; they do not take up space in your generated code, so use them abundantly - useful comments greatly increase the readability and maintainability of source code.

Comment text is any sequence of characters. A comment can appear on a line with other statements, but it must be the last thing on that line, and a colon must precede it. For example, the assignment below will not be compiled or executed because the compiler cannot tell where the comment ends and the statement begins:

```
REM now add the numbers: a = b + c
```

The following works:

```
a = b + c : REM now add the numbers
```

The apostrophe (') is an alternate form of REM. When you use an apostrophe, you do not need a colon to separate the remark from the other statements on the same line.

When using the Inline Assembler, use the semi-colon (;) to indicate that the remainder of the line should be ignored. An apostrophe (') can still be used for comments, however.

In addition, the compiler treats text that appears after the line continuation character as a remark. However, we still recommend that such comments are preceded by a REM or an apostrophe (') symbol to clearly distinguish remarks from the actual code. For example:

```
DECLARE FUNCTION Call32& _   The prototype
  LIB "CALL32.DLL" _ The DLL name
  ALIAS "Call32" _    ' The exported name
  (Param1 AS ANY, _  ' 1st parameter
  BYVAL id&) ' 2nd parameter
```

For situations where a large section of code needs to be REMmed out (yet preserved within the source code file), it is often easier to enclose the code with #IF 0/#ENDIF metastatements. For example:

```
#IF 0                ' Exclude the following lines
  Code and text in between the #IF 0 and #ENDIF
  metastatements is ignored by the compiler.
  DIM a$(1 TO 1000) ' This line is ignored too.
  INCR x&           ' As is this line!
#ENDIF
```

Since the #IF expression evaluates to false (zero), this forces the compiler to exclude the enclosed block of code from the compilation process, in exactly the same way as if a REM statement had been prefixed to each line.

See also Long Lines

Example

```
x% = 10          : REM This is a comment
y% = 20          ' This is another form of comment
! MOV EAX,"ABCD" ; An Inline Assembler comment
```

REMAIN$ function

REMAIN$ function

Purpose Return the portion of a

following the first occurrence of a character or group of characters.

Syntax `a$ = REMAIN$([Start,] MainStr, [ANY] MatchStr)`

Remarks REMAIN$ is a complement to the EXTRACT$ function. *MainStr* is searched for the string specified in *MatchStr*. If found, all characters after *MatchStr* are returned. If *MatchStr* is not present in *MainStr*, or either string parameter is nul, then a nul (zero-length) is returned.

Start is an optional starting position to begin searching. If Start is not specified, position 1 will be used. If *Start* is zero, a nul string is returned. If *Start* is negative, the starting position is counted from right to left: if -1, the search begins at the last character; if -2, the second to last, and so forth.

If the ANY keyword is included, *MatchStr* specifies a list of single characters to be searched for individually. A match on any one of them will cause the operation to be performed up to that character.

See also EXTRACT$, LEFT$, LTRIM$, MID$, REMOVE$, REPLACE, RIGHT$, RTRIM$, TALLY, TRIM$, VERIFY

Example

```
a$ = REMAIN$("I think, therefore I am hungry", ",")
Result  " therefore I am hungry"
```

REMOVE$ function

REMOVE$ function

Purpose Return a copy of a

with characters or strings removed.

Syntax `x$ = REMOVE$(MainString, [ANY] MatchString)`

Remarks The REMOVE$ function has the following parts:

MainString The string expression from which to remove characters.

MatchString The string expression to remove all occurrences of. If *MatchString* is not present in *MainString*, all of *MainString* is returned intact.

ANY If the ANY keyword is included, *MatchString* specifies a list of single characters to be searched for individually, a match on any one of which will cause that character to be removed from the result.

Restrictions REMOVE is case-sensitive.

See also CLIP$, EXTRACT$, INSTR, LTRIM$, MID$, REPLACE, RETAIN$, RIGHT$, RTRIM$, SHRINK$, TALLY, TRIM$, UNWRAP$, VERIFY

Example

```
' The following returns "aadabra",
' removing the string "bac"
x$ = REMOVE$("abacadabra", "bac")

' The following returns "dr",
' removing all "b", "a", and "c"
x$ = REMOVE$("abacadabra", ANY "bac")
```

REPEAT$ function

REPEAT$ function

Purpose Return a

consisting of multiple copies of the specified string.

Syntax `s$ = REPEAT$(count&, string_expr)`

Remarks The REPEAT$ function has the following parts:

count& Is an

expression, constant or variable, specifying the number of copies of *string_expr* to be included in the result. REPEAT$ is very similar to STRING$ (which makes multiple copies of a single character).

string_expr The string to be duplicated.

See also BUILD$, CHR$, GUID$, NUL$, SPACE$, STRING$

Example `x$ = REPEAT$(5, "<*> ")`

Result `<*> <*> <*> <*> <*>`

REPLACE statement

REPLACE statement

Purpose Within a specified

, replace all occurrences of one string with another string.

Syntax `REPLACE [ANY] MatchString WITH NewString IN MainString`

Remarks The REPLACE statement replaces all occurrences of *MatchString* in *MainString* with *NewString.* The replacement can cause *MainString* to grow or condense in size. *MainString* must be a string variable; *MatchString* and *NewString* may be string expressions. REPLACE is case-sensitive. When a match is found, the scan for the next match begins at the position immediately following the prior match.

ANY — If you use the ANY option, within *MainString*, each occurrence of each character in *MatchString* will be replaced with the corresponding character in *NewString*. In this case, *MatchString* and *NewString* must be the same length, because there is a one-to-one correspondence between their characters.

See also — EXTRACT$, INSTR, LTRIM$, MID$, REMOVE$, RETAIN$, RIGHT$, RTRIM$, SHRINK$, TALLY, TRIM$, UNWRAP$, VERIFY

Example

```
A$ = "abacadabra"
'now replace "bac" with "----bac----"
REPLACE "bac" WITH "----bac----" IN A$

A$ = "abacadabra"
'now replace all "b", "a", and "c" with "*"
REPLACE ANY "bac" WITH "***" IN A$
```

RESET statement

RESET statement

Purpose — Set a scalar (non-array) variable, Variant, User-Defined Type, individual array element (or an entire array) to zero or null/empty. RESET does not deallocate the actual memory used (with the exception of dynamic string array data, which is automatically deallocated).

Syntax

```
RESET variable [, ...]
RESET array() [, ...]
RESET array(index) [, ...]
```

Remarks — If *variable* is numeric, it is set to zero. If *variable* is a dynamic string, it is set to null (""; an empty string). If *variable* is a nul-terminated string, the first byte is set to nul ($NUL). If *variable* is a fixed-length string or User-Defined Type/Union, all bytes in *variable* are set to nul, or CHR$(0). If *variable* is a Variant, it is cleared and set to data type %VT_EMPTY.

If *array()* is

, all elements are set to zero; otherwise all elements are set to zero/null. If an array *index* value is specified within the parentheses, just that array element is set to zero/null, as if it were a scalar (non-array) variable.

RESET also works with *absolute arrays*, clearing the contents to zeroes or empty strings. For more information on absolute arrays, please refer to the DIM statement.

See also — ARRAYATTR, DIM, ERASE, LET, LET (with Types), LET (with Variants), REDIM

RESOURCE$ function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

RESOURCE$ function New!

Purpose Returns predefined resource data.

Syntax
```
r$  = RESOURCE$(RCDATA, ResID)
s$$ = RESOURCE$(STRING, ResID%)
```

Remarks You can embed data into your EXE or DLL with the #RESOURCE metastatement. While the data can be represented in several different data types, two are designed to be retrieved directly for your own purposes: RCDATA and STRING. In both cases, this data is returned as a variable-length string so you can manipulate it and use it as you wish. The specific resource you wish to retrieve is specified by the *ResID*. If the ID you request is not present, a nul (zero-length) string is returned.

RCDATA This resource contains raw data of any type. It is always stored byte-by-byte, just as it was originally created at the time of compilation. Generally speaking, this type of data should be assigned to an ANSI string variable so no Unicode conversions are performed. The *ResID* which identifies this resource may be a numeric value between 0 and 65535, or an alphanumeric label which is passed to the function as a string expression (string literal, variable, etc.)

STRING This resource contains predefined strings in a string table. Each string is identified by a resource ID number in the range of 0 to 65535. This number is used as the *ResID%* to determine which string will be retrieved. Because of the format in which Windows stores the strings in tables, only integral numeric ID's may be used. All resource strings are saved internally in wide Unicode format.

See also #RESOURCE

RESUME statement

RESUME statement IMPROVED

Purpose Restart program execution after error handling with ON ERROR GOTO.

Syntax
```
RESUME
RESUME NEXT
RESUME FLUSH
RESUME <Label>
```

Remarks The RESUME statement is used to continue execution of a program after a run-time error has been trapped and processed with an ON ERROR handler. RESUME (in any form) tells PowerBASIC that error processing has been completed, and it is now time to continue normal execution of the programming. Whenever an error is trapped and processed by ON ERROR GOTO, execution of a matching RESUME is mandatory.

RESUME

If the first form of RESUME is used (without any modifier), the statement which generated the error is executed again and program flow continues normally. Be certain that you've corrected the condition which generated the error in the first place before you do this!

RESUME NEXT

If you execute RESUME NEXT, program execution continues on the line immediately following the one which generated the error. Program flow continues normally after that. Be certain that your error handler did whatever was necessary to substitute new actions to replace what was expected from the code which errored.

RESUME FLUSH

If you execute RESUME FLUSH, there is no transfer of control to a different line.

Program execution simply continues on the line immediately following the RESUME FLUSH.

RESUME <*Label*>

If a label is specified, program execution continues at the specified label location. The label must be "local"; that is, it must be located within the same procedure as the RESUME.

Restrictions ON ERROR and RESUME may not be used within a TRY/END TRY block or a FASTPROC procedure.

See also ERL, ERR, ERROR, Error Overview, ERROR$, Error Trapping, ON ERROR

Example See the examples in Error Trapping.

RESUME FLUSH statement

RESUME statement IMPROVED

Purpose Restart program execution after error handling with ON ERROR GOTO.

Syntax

```
RESUME
RESUME NEXT
RESUME FLUSH
RESUME <Label>
```

Remarks The RESUME statement is used to continue execution of a program after a run-time error has been trapped and processed with an ON ERROR handler. RESUME (in any form) tells PowerBASIC that error processing has been completed, and it is now time to continue normal execution of the programming. Whenever an error is trapped and processed by ON ERROR GOTO, execution of a matching RESUME is mandatory.

RESUME

If the first form of RESUME is used (without any modifier), the statement which generated the error is executed again and program flow continues normally. Be certain that you've corrected the condition which generated the error in the first place before you do this!

RESUME NEXT

If you execute RESUME NEXT, program execution continues on the line immediately following the one which generated the error. Program flow continues normally after that. Be certain that your error handler did whatever was necessary to substitute new actions to replace what was expected from the code which errored.

RESUME FLUSH

If you execute RESUME FLUSH, there is no transfer of control to a different line. Program execution simply continues on the line immediately following the RESUME FLUSH.

RESUME <*Label*>

If a label is specified, program execution continues at the specified label location. The label must be "local"; that is, it must be located within the same procedure as the RESUME.

Restrictions ON ERROR and RESUME may not be used within a TRY/END TRY block or a FASTPROC procedure.

See also ERL, ERR, ERROR, Error Overview, ERROR$, Error Trapping, ON ERROR

Example See the examples in Error Trapping.

RESUME NEXT statement

RESUME statement IMPROVED

Purpose Restart program execution after error handling with ON ERROR GOTO.

Syntax

```
RESUME
RESUME NEXT
RESUME FLUSH
RESUME <Label>
```

Remarks The RESUME statement is used to continue execution of a program after a run-time error has been trapped and processed with an ON ERROR handler. RESUME (in any form) tells PowerBASIC that error processing has been completed, and it is now time to continue normal execution of the programming. Whenever an error is trapped and processed by ON ERROR GOTO, execution of a matching RESUME is mandatory.

RESUME

If the first form of RESUME is used (without any modifier), the statement which generated the error is executed again and program flow continues normally. Be certain that you've corrected the condition which generated the error in the first place before you do this!

RESUME NEXT

If you execute RESUME NEXT, program execution continues on the line immediately following the one which generated the error. Program flow continues normally after that. Be certain that your error handler did whatever was necessary to substitute new actions to replace what was expected from the code which errored.

RESUME FLUSH

If you execute RESUME FLUSH, there is no transfer of control to a different line. Program execution simply continues on the line immediately following the RESUME FLUSH.

RESUME <*Label*>

If a label is specified, program execution continues at the specified label location. The label must be "local"; that is, it must be located within the same procedure as the RESUME.

Restrictions ON ERROR and RESUME may not be used within a TRY/END TRY block or a FASTPROC procedure.

See also ERL, ERR, ERROR, Error Overview, ERROR$, Error Trapping, ON ERROR

Example See the examples in Error Trapping.

RESUME <Label> statement

RESUME statement IMPROVED

Purpose Restart program execution after error handling with ON ERROR GOTO.

Syntax

```
RESUME
RESUME NEXT
RESUME FLUSH
RESUME <Label>
```

Remarks The RESUME statement is used to continue execution of a program after a run-time error has been trapped and processed with an ON ERROR handler. RESUME (in any form) tells PowerBASIC that error processing has been completed, and it is now time to continue normal execution of the programming. Whenever an error is trapped and processed by ON ERROR GOTO, execution of a matching RESUME is mandatory.

RESUME

If the first form of RESUME is used (without any modifier), the statement which generated the error is executed again and program flow continues normally. Be certain that you've corrected the condition which generated the error in the first place before you do this!

RESUME NEXT

If you execute RESUME NEXT, program execution continues on the line immediately following the one which generated the error. Program flow continues normally after that. Be certain that your error handler did whatever was necessary to substitute new actions to replace what was expected from the code which errored.

RESUME FLUSH

If you execute RESUME FLUSH, there is no transfer of control to a different line. Program execution simply continues on the line immediately following the RESUME FLUSH.

RESUME <*Label*>

If a label is specified, program execution continues at the specified label location. The label must be "local"; that is, it must be located within the same procedure as the RESUME.

Restrictions ON ERROR and RESUME may not be used within a TRY/END TRY block or a FASTPROC procedure.

See also ERL, ERR, ERROR, Error Overview, ERROR$, Error Trapping, ON ERROR

Example See the examples in Error Trapping.

RETAIN$ function

RETAIN$ function

Purpose Return a

containing only the characters contained in a specified match string. All other characters are removed..

Syntax `sResult$ = RETAIN$(mainstr$, [ANY] matchstr$)`

Remarks RETAIN$ returns a string consisting of zero or more copies of the complete expression *matchstr$* which are found in *mainstr$*. All other characters are removed.

ANY If the ANY option is included, *matchstr$* specifies a list of single characters to be retained, if they are found in *mainstr$*.

Restrictions If *matchstr$* is an empty string, RETAIN$ returns an empty string.

See also EXTRACT$, REMAIN$, REMOVE$, REPLACE

Example

```
a$ ="<p>1234567890<ak;lk;l>1234567890</p>"
b$ = RETAIN$(a$, ANY "<;/p>")
c$ = RETAIN$(a$, ANY "0123456789")
```

Result

```
b$ contains "<p><;;></p>"
c$ contains "12345678901234567890"
```

RETURN statement

RETURN statement IMPROVED

Purpose Return from a (GOSUB) subroutine to its caller.

Syntax
```
RETURN
RETURN FLUSH
```

Remarks RETURN terminates the execution of a subroutine, and passes control to the statement directly following the calling GOSUB statement.

RETURN FLUSH removes the most recent return address from the system stack and program flow continues normally after the RETURN FLUSH.

Performing either form of RETURN without a corresponding GOSUB can cause unpredictable behavior and difficult-to-track errors. This includes the possibility of a General Protection Fault (GPF).

See also CALL, GOSUB, GOTO, ON ERROR, SUB/END SUB

Example See the example in GOSUB.

RETURN FLUSH statement

RETURN statement IMPROVED

Purpose Return from a (GOSUB) subroutine to its caller.

Syntax
```
RETURN
RETURN FLUSH
```

Remarks RETURN terminates the execution of a subroutine, and passes control to the statement directly following the calling GOSUB statement.

RETURN FLUSH removes the most recent return address from the system stack and program flow continues normally after the RETURN FLUSH.

Performing either form of RETURN without a corresponding GOSUB can cause unpredictable behavior and difficult-to-track errors. This includes the possibility of a General Protection Fault (GPF).

See also CALL, GOSUB, GOTO, ON ERROR, SUB/END SUB

Example See the example in GOSUB.

RGB function

RGB function

Purpose Create an RGB color value from 3 primary color values or from a BGR value.

Syntax
```
result& = RGB(red&, green&, blue&)
result& = RGB(bgrexpr&)
```

Remarks An RGB value is a long integer value in the range of 0 to &H00FFFFFF. It is used to specify a very precise color to various PowerBASIC functions and Windows API functions. The lowest three bytes of the value each specify the intensity of a primary color which combine to form the resultant color. Byte 1 (lowest) represents the red component, byte 2 the green, and byte 3 the blue. They can each take on a value in the range of 0 to 255. Byte 4 (highest) is always 0. When used with 3 parameters, the RGB() function creates an RGB value from the three component values.

Some Windows API functions, namely those which reference Device Independent Bitmaps (DIB), require that the colors be specified in the reverse sequence (Blue-Green-Red instead of Red-Green-Blue). In order to maximize performance and execution speed, PowerBASIC statements and functions which reference these structures also use the BGR format. These include GRAPHIC GET BITS and GRAPHIC SET BITS.

When used with one parameter, this function translates a BGR value to its RGB equivalent by swapping the first byte with the third byte, and returning the result.

For example, the BGR value of red is &HFF0000. RGB() translates it to &H0000FF. Calling BGR() with that value converts it back to &HFF0000.

See also Built In RGB Color Equates, BGR

RIGHT$ function

RIGHT$ function

Purpose Return the rightmost *n* characters of a

.

Syntax ***s$*** **= RIGHT$(*string_expression, n&*)**

Remarks If *n&* is positive, RIGHT$ returns the indicated number of characters from the string, starting from the right and working left. If *n&* greater than the length of string_expression, all of string_expression is returned.

If *n&* is 0, RIGHT$ returns an empty string. If *n&* is negative, it is interpreted as (LEN(*string_expression*) - ABS(*n&*)). For example, RIGHT$("1234567890", -2) returns "34567890".

See also EXTRACT$, INSTR, LEFT$, LTRIM$, MID$, REMOVE$, REPLACE, RTRIM$, SPLIT, TALLY, TRIM$, VERIFY

Example

```
' Demonstrate LEFT$ and RIGHT$ functions
DIM aString$, x$, n AS LONG
aString$ = "ABCDEFGHIJKLMNOP"
FOR n = 1 TO 14 STEP 2
  x$ = LEFT$(aString, n) + SPACE$(28 - n * 2) + RIGHT$(aString, n)
NEXT n
```

RMDIR statement

RMDIR statement

Purpose Delete a disk directory (like the DOS RMDIR command).

Syntax **RMDIR *path***

Remarks *path* is a directory path, which may include a drive specification. RMDIR deletes the directory indicated by *path*.

This statement works like the DOS "RMDIR" or "RD" commands. As with the DOS commands, the *path* must specify a valid, empty directory, other than the default (current) directory. Otherwise, a run-time Error 75 occurs ("Path/file access error").

RMDIR can use Long File Names (LFNs).

See also CHDIR, KILL, MKDIR

Example

```
DirectoryName$ = "\TEMP"
RMDIR DirectoryName$
```

RND function

RND function

Purpose Return a random number.

Syntax

```
y = RND
y = RND(a, b)
y = RND(numeric_expression)
```

Remarks Floating point mode: RND returns a random value that is less than 1, but greater than or equal to 0. Numbers generated by RND aren't really random, but are the result of applying a pseudo-random transformation algorithm to a starting ("seed") value. Given the same seed, PowerBASIC's RND algorithm always produces the same sequence of "random" numbers. The pseudo-random value is calculated internally as a single precision value, but returned as an extended precision representation so it can be readily used in any situation.

Integral Range mode: RND(*a*, *b*) returns a Long-integer in the range of *a* to *b* inclusive. *a* and *b* can each be a numeric literal or a numeric expression that evaluates within the range of a Long-integer (-2,147,483,648 to 2,147,483,647).

Special effects mode: When used with a single numeric expression argument, the value returned by RND depends on the optional numeric value you supply as the argument, as follows:

With no argument, or with a positive argument, RND generates the next number in sequence based on the initial seed value. With an argument of 0, RND repeats the last number generated. A negative argument causes the random number generator to be re-seeded, so subsequent uses of RND with no argument or with a positive argument result in a new sequence of values.

Do not use 0 or negative value arguments in special effects mode unless you are looking for the special effects those argument values produce.

The random number generator can be reset back to the default seed using the following statement:

```
RANDOMIZE CVS(CHR$(255,255,255,255))
```

Note that each thread has its own, independent random number seed. See the discussion under RANDOMIZE for additional information on seeding the random number generator.

Example See the example under RANDOMIZE.

ROTATE statement

ROTATE statement

Purpose Rotate the bits in an variable.

Syntax

```
ROTATE {LEFT | RIGHT} ivar, count
```

Remarks *ivar* must be one of the integral-class variable types: Byte, Word, Integer, Double-word, Long-integer, or Quad-integer. *count* is the number of bits by which to rotate *ivar*. ROTATE rotates all the bits in *ivar* without special regard to the sign bit of a signed integral-class variable.

See also BIT function, BIT statement, BITS, SHIFT

Example

```
i? = 221            ' binary: 1 1 0 1 1 1 0 1
ROTATE RIGHT i?, 1  ' binary: 1 1 1 0 1 1 1 0
```

ROUND function

ROUND function

Purpose Round a numeric value to a specified number of decimal places.

Syntax `x = ROUND(numeric_expression, n)`

Remarks *n* is an

expression specifying the number of decimal places required in the result. ROUND is especially useful in cases where you have a variable in Single, Double, or Extended-precision, and you want to put it into a Currency variable or display it, rounded to a specific number of decimal places.

Rounding is done according to the "banker's rounding" principle: if the fractional digit being rounded off is exactly five, with no trailing digits, the number is rounded to the nearest even number. This provides better results, on average, than the simple "round up at five" approach.

```
A% = ROUND(0.5, 0)            ' 0
A% = ROUND(1.5, 0)            ' 2
A% = ROUND(2.5, 0)            ' 2
A% = ROUND(2.51, 0)           ' 3
```

See also CEIL, FIX, FORMAT$, INT, USING$

RSET statement

RSET statement

Purpose Right justify a

into the space of a string variable or User-Defined Type.

Syntax `RSET [ABS] result_var = string_expression [USING ustring_expression]`

Remarks RSET right-aligns a string within the space of another string, or within a variable of a User-Defined Type (UDT).

ABS If ABS is specified, or *ustring_expression* is null (empty), RSET leaves the padding positions unchanged from their original content, rather than replacing them with spaces.

USING If *string_expression* is shorter then *result_var*, RSET right-justifies *string_expression* within *result_var,* and pads remaining character positions on the left side using the first character in *ustring_expression* or spaces if not specified or is null (empty).

If *string_expression* is longer than *result_var*, RSET truncates *string_expression* from the right until it fits in *result_var*.

RSET can be used to assign the content of a User-Defined Type to a User-Defined Type variable of a different class, or assign a dynamic string to a User-Defined Type. For example:

```
RSET MyUDT = STRING$(LEN(MyUDT), 0)
RSET MyUDT = b$
```

LSET works in a similar manner, but left-aligns *string_expression*; CSET performs center-justification.

See also CSET, CSET$, GET, LET, LET (with Types), LSET, LSET$, PUT, RESET, RSET$, STRINSERT$, TYPE SET

Example

```
a$ = SPACE$(20)
RSET a$ = "Right-align"
' result "         Right-align"
```

```
RSET a$ = "Right-align" USING "*"
' result "*********Right-align"
```

RSET$ function

RSET$ function

Purpose Return a

containing a right-justified (padded) string.

Syntax `a$ = RSET$(string_expression, strlen& [USING ustring_expression])`

Remarks RSET$ right-aligns the string *string_expression* into a string of *strlen&* characters.

USING If *ustring_expression* is null (empty) or is not specified, RSET$ pads *string_expression* with space characters. Otherwise, RSET$ pads the string with the first character of *ustring_expression*.

If *string_expression* is shorter then *strlen&*, RSET$ right-justifies *string_expression* within the assigned string variable (*a$*), padding the left side as described above; otherwise, RSET$ returns the left-most *strlen&* bytes of *string_expression*.

See also CSET, CSET$, GET, LET, LSET, LSET$, PUT, RESET, RSET, STRINSERT$, TYPE SET

Example

```
a$ = RSET$("PowerBASIC", 20)
' result: "          PowerBASIC"

a$ = RSET$("PowerBASIC",20 USING "*")
' result: "**********PowerBASIC"
```

RTRIM$ function

RTRIM$ function

Purpose Return a copy of a

with trailing characters or strings removed.

Syntax `x$ = RTRIM$(MainString [, [ANY] MatchString])`

Remarks *MainString* is the string expression from which to remove characters, and *MatchString* is the string expression specifying the characters that should be removed from the right hand side of *MainString*.

If *MatchString* is not specified, RTRIM$ removes trailing spaces. RTRIM$ returns a sub-string of *MainString*, from the beginning of the string to the character preceding the consecutive occurrences of *MatchString* (or space), which continues to the end of the original string. If *MatchString* (or a space) is not present at the end of *MainString*, all of *MainString* is returned.

RTRIM$ is case-sensitive.

ANY If the ANY keyword is included, *MatchString* specifies a list of single characters to be searched for individually - a match on any one of which as a trailing character will cause the character to be removed from the result.

See also CLIP$, EXTRACT$, INSTR, LEFT$, LTRIM$, MID$, REMOVE$, REPLACE, RIGHT$, STRDELETE$, STRINSERT$, STRREVERSE$, TALLY, TRIM$, VERIFY

Example

```
' returns "abacadabra" (match on spaces)
x$ = RTRIM$("abacadabra   ")

' returns "abacadabra   " (no match on " cad")
x$ = RTRIM$("abacadabra   ", " cad")
```

```
' returns "abacadabr" (match on " " and "a")
x$ = RTRIM$("abacadabra   ", ANY " cad")
```

SCROLLBAR GET PAGESIZE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

SCROLLBAR statement

Purpose Manipulate a SCROLLBAR control. A ScrollBar is a control that allows the user to scroll a data object to bring into view portions of the object that extend beyond the borders of the window.

Syntax

```
SCROLLBAR GET PAGESIZE hDlg, id& TO datav&
SCROLLBAR GET POS hDlg, id& TO datav&
SCROLLBAR GET RANGE hDlg&, id& TO LoDatav&, HiDatav&
SCROLLBAR GET TRACKPOS hDlg, id& TO datav&
SCROLLBAR SET PAGESIZE hDlg, id&, pagesize&
SCROLLBAR SET POS hDlg, id&, position&
SCROLLBAR SET RANGE hDlg, id&, lolimit&, hilimit&
```

hDlg Handle of the dialog that owns the ScrollBar.

id& The control identifier assigned with CONTROL ADD SCROLLBAR.

Remarks In each of the following samples and descriptions, the SCROLLBAR control that is the subject of the statement is identified by the handle of the dialog that owns the ScrollBar (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD SCROLLBAR. To alter the color of the bar or the background, use CONTROL SET COLOR.

SCROLLBAR GET PAGESIZE *hDlg*, *id&* TO *datav&*

The current page size of the ScrollBar is retrieved and assigned to the variable designated by *datav&*. Upon ScrollBar creation, the default page size is 10.

SCROLLBAR GET POS *hDlg*, *id&* TO *datav&*

The current position of the ScrollBar is retrieved and assigned to the variable designated by *datav&*. Upon ScrollBar creation, the default position is 0.

SCROLLBAR GET RANGE *hDlg*, *id&* TO *LoDatav&*, *HiDatav&*

The current range of the ScrollBar is retrieved and assigned to the variables designated by *LoDatav&* and *HiDatav&*. Upon ScrollBar creation, the default ScrollBar range is 0 to 100.

SCROLLBAR GET TRACKPOS *hDlg*, *id&* TO *datav&*

The current position of the scroll box, being dragged by the user, is retrieved and assigned to the variable designated by *datav&*. This is normally read while responding to the %SB_THUMBPOSITION or the %SB_THUMBTRACK messages. The TRACKPOS is then used to move the scroll position with SCROLLBAR SET POS.

SCROLLBAR SET PAGESIZE *hDlg, id&, pagesize&*

The current page size of the ScrollBar is set to the value of the parameter *pagesize&*, and the bar is redrawn to reflect the new position.

SCROLLBAR SET POS *hDlg, id&, position&*

The current position of the ScrollBar is set to the value of the parameter *position&*, and the bar is redrawn to reflect the new position.

SCROLLBAR SET RANGE *hDlg, id&, lolimit&, hilimit&*

The range for the ScrollBar is specified to be from *lolimit&* to *hilimit&*. If *lolimit&* is greater than *hilimit&*, the results are undefined.

```
SCROLLBAR GET PAGESIZE hDlg, id& TO datav&
SCROLLBAR GET POS hDlg, id& TO datav&
SCROLLBAR GET RANGE hDlg&, id& TO LoDatav&, HiDatav&
SCROLLBAR GET TRACKPOS hDlg, id& TO datav&
SCROLLBAR SET PAGESIZE hDlg, id&, pagesize&
SCROLLBAR SET POS hDlg, id&, position&
SCROLLBAR SET RANGE hDlg, id&, lolimit&, hilimit&
```

hDlg Handle of the dialog that owns the ScrollBar.

id& The control identifier assigned with CONTROL ADD SCROLLBAR.

Remarks In each of the following samples and descriptions, the SCROLLBAR control that is the subject of the statement is identified by the handle of the dialog that owns the ScrollBar (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD SCROLLBAR. To alter the color of the bar or the background, use CONTROL SET COLOR.

SCROLLBAR GET PAGESIZE *hDlg, id&* TO *datav&*

The current page size of the ScrollBar is retrieved and assigned to the variable designated by *datav&*. Upon ScrollBar creation, the default page size is 10.

SCROLLBAR GET POS *hDlg, id&* TO *datav&*

The current position of the ScrollBar is retrieved and assigned to the variable designated by *datav&*. Upon ScrollBar creation, the default position is 0.

SCROLLBAR GET RANGE *hDlg, id&* TO *LoDatav&, HiDatav&*

The current range of the ScrollBar is retrieved and assigned to the variables designated by *LoDatav&* and *HiDatav&*. Upon ScrollBar creation, the default ScrollBar range is 0 to 100.

SCROLLBAR GET TRACKPOS *hDlg, id&* TO *datav&*

The current position of the scroll box, being dragged by the user, is retrieved and assigned to the variable designated by *datav&*. This is normally read while responding to the %SB_THUMBPOSITION or the %SB_THUMBTRACK messages. The TRACKPOS is then used to move the scroll position with SCROLLBAR SET POS.

SCROLLBAR SET PAGESIZE *hDlg, id&, pagesize&*

The current page size of the ScrollBar is set to the value of the parameter *pagesize&*, and the bar is redrawn to reflect the new position.

SCROLLBAR SET POS *hDlg, id&, position&*

The current position of the ScrollBar is set to the value of the parameter *position&*, and the bar is redrawn to reflect the new position.

SCROLLBAR SET RANGE *hDlg, id&, lolimit&, hilimit&*

The range for the ScrollBar is specified to be from *lolimit&* to *hilimit&*. If *lolimit&* is greater than *hilimit&*, the results are undefined.

Example

SCROLLBAR statement

Purpose Manipulate a SCROLLBAR control. A ScrollBar is a control that allows the user to scroll a data object to bring into view portions of the object that extend beyond the borders of the window.

Syntax

```
SCROLLBAR GET PAGESIZE hDlg, id& TO datav&
SCROLLBAR GET POS hDlg, id& TO datav&
SCROLLBAR GET RANGE hDlg&, id& TO LoDatav&, HiDatav&
SCROLLBAR GET TRACKPOS hDlg, id& TO datav&
SCROLLBAR SET PAGESIZE hDlg, id&, pagesize&
SCROLLBAR SET POS hDlg, id&, position&
SCROLLBAR SET RANGE hDlg, id&, lolimit&, hilimit&
```

hDlg Handle of the dialog that owns the ScrollBar.

id& The control identifier assigned with CONTROL ADD SCROLLBAR.

Remarks In each of the following samples and descriptions, the SCROLLBAR control that is the subject of the statement is identified by the handle of the dialog that owns the ScrollBar (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD SCROLLBAR. To alter the color of the bar or the background, use CONTROL SET COLOR.

SCROLLBAR GET PAGESIZE *hDlg, id&* TO *datav&*

The current page size of the ScrollBar is retrieved and assigned to the variable designated by *datav&*. Upon ScrollBar creation, the default page size is 10.

SCROLLBAR GET POS *hDlg, id&* TO *datav&*

The current position of the ScrollBar is retrieved and assigned to the variable designated by *datav&*. Upon ScrollBar creation, the default position is 0.

SCROLLBAR GET RANGE *hDlg, id&* TO *LoDatav&, HiDatav&*

The current range of the ScrollBar is retrieved and assigned to the variables designated by *LoDatav&* and *HiDatav&*. Upon ScrollBar creation, the default ScrollBar range is 0 to 100.

SCROLLBAR GET TRACKPOS *hDlg, id&* TO *datav&*

The current position of the scroll box, being dragged by the user, is retrieved and assigned to the variable designated by *datav&*. This is normally read while responding to the %SB_THUMBPOSITION or the %SB_THUMBTRACK messages. The TRACKPOS is then used to move the scroll position with SCROLLBAR SET POS.

SCROLLBAR SET PAGESIZE *hDlg, id&, pagesize&*

The current page size of the ScrollBar is set to the value of the parameter *pagesize&*, and the bar is redrawn to reflect the new position.

SCROLLBAR SET POS *hDlg, id&, position&*

The current position of the ScrollBar is set to the value of the parameter *position&*, and the bar is redrawn to reflect the new position.

SCROLLBAR SET RANGE *hDlg, id&, lolimit&, hilimit&*

The range for the ScrollBar is specified to be from *lolimit&* to *hilimit&*. If *lolimit&* is greater than *hilimit&*, the results are undefined.

See also Dynamic Dialog Tools, CONTROL ADD SCROLLBAR, CONTROL SET COLOR

SEEK function

SEEK function

Purpose Return the location within a file where the next I/O operation will take place.

Syntax ***position&&* = SEEK([#] *filenum&*)**

Remarks If file *filenum&* was opened in random-access mode, SEEK returns the record number of the next record to be written or read as a Quad-integer (64-bit) value. If the file was opened in any other mode, SEEK returns the byte position of the next byte to be written or read, as a Quad-integer (64-bit) value. The Number symbol (#) is optional, but recommended for clarity.

The beginning byte position (for binary and sequential files) or record position (for random-access files) may be 0 or 1, depending on the BASE option used when the file was initially Opened. The default, if no BASE is specified, is a starting position of 1.

PowerBASIC recommends using the SEEK function over the (more complex) LOC function used in prior versions of PowerBASIC. LOC remains supported for compatibility with older versions of BASIC, but it is likely that LOC may be removed in future versions of PowerBASIC.

See also EOF, FILEATTR, GET$, GET$$, LOC, LOF, OPEN, PUT$, PUT$$, SEEK statement

Example

```
RANDOMIZE TIMER
OPEN "OUTPUT.TXT" FOR OUTPUT AS #1
PRINT #1, STRING$(RND * 80, RND * 255);
position&& = SEEK(1)
CLOSE #1
```

SEEK statement

SEEK statement

Purpose Set the position in a file for the next input or output operation.

Syntax **SEEK [#]** ***filenum&, position&&***

Remarks SEEK sets the file pointer position of file *filenum&* to *position&&*. *position&&* is a Quad-integer variable, constant, or expression.

The next GET$ or PUT$ performed on the file *filenum&* will occur *position&&* bytes (or records) deep into the file. If file *filenum&* was opened in binary or sequential mode, *position&&* indicates the new file position in bytes; for random-access files, *position* is in records.

The first byte position (for binary and sequential files) or record position (for random-access files) may be 0 or 1, depending on the BASE option used when the file was initially Opened. If no BASE was specified, the default position is 1.

Use the SEEK function to determine a binary file's current pointer position, and LOF to determine its length. Seeking past the end of a file does not produce an error, but no data can be read from beyond the true end of the file.

See also EOF, FILEATTR, GET$, GET$$, LOC, LOF, OPEN, PUT$, PUT$$, SEEK function, SETEOF

Example

```
SUB CreateFile
  ' Open a binary file and writes 75 chars to it.
  LOCAL I&
  OPEN "SEEK.DTA" FOR BINARY AS #1
  FOR I& = 48 TO 122
    PUT$ 1, CHR$(I&)
  NEXT I&
END SUB

FUNCTION ReadIt$(Start&&, qSize&&)
  ' SEEK to the correct position in the file,
  ' which was previously opened in the CreateFile SUB.
  SEEK 1, Start&&
  I&& = 1
  TempStr$ = ""
  ' Read in the indicated data - don't read past end of file.
  WHILE (ISFALSE EOF(1)) AND (I&& <= qSize&&)
    GET$ 1, 1, Char$
    TempStr$ = TempStr$ + Char$
    INCR I&&
  WEND
  ReadIt$ = TempStr$    ' assign function's result
END FUNCTION
```

SELECT CASE/END SELECT block

SELECT CASE/END SELECT block IMPROVED

Purpose Control program flow based on the value of an expression.

Syntax

```
SELECT CASE [AS] [LONG | CONST | CONST$ | CONST$$] expression
CASE [IS] testlist
  [statements]
[CASE [IS] testlist
  [statements]]
[CASE ELSE
  [statements]]
END SELECT
```

Remarks *testlist* is one or more tests, separated by commas, to be performed on *expression*. *expression* can be either

or .

When a SELECT statement is encountered, *expression* is evaluated using the *testlist* in the first CASE clause. If the evaluation is FALSE, the evaluation is repeated using the next *testlist*. As soon as an evaluation is TRUE (non-zero), the statements following that CASE clause are executed, up to the next CASE clause.

Execution then passes to the statement following the END SELECT statement. If none of the evaluations is TRUE, the statements following the optional CASE ELSE clause are executed.

The tests that may be performed by a CASE clause include: equality, inequality, greater than, less than, and range ("from-to") testing. The SELECT CASE block can do string or numeric tests, but these cannot be interchanged.

Examples of numeric CASE clause tests include:

```
SELECT CASE numeric_expression
  CASE > b         ' relational; is expression > b?
  CASE 14          ' equality (= is assumed); is expression equal to
14?
  CASE b TO 99     ' range; is expression between the value of the
                   ' variable b and 99 (inclusive)?
  CASE 14, b       ' two equality tests; is expression equal to
                   ' 14 or equal to b?
  CASE 25 TO 99,14 ' combination range and equality;  is expression
                   ' between 25 and 99  (inclusive) or equal to 14?
```

Examples of string CASE clause tests include:

```
SELECT CASE string_expression
  CASE > b$           ' relational; is expression > b$?
  CASE "X"            ' equality (= is assumed); is expression equal
                      ' to "X"?
  CASE "A" TO "C"     ' range; is expression between "A" and
                      ' "C"(inclusive)?
  CASE "Y", b$        ' two equality tests; is expression equal to
                      ' "Y" or equal to b$?
  CASE "A" TO "C","Q" ' combination range and equality; is expression
                      ' between "A" and "C"  (inclusive) or equal
                      ' to "Q"?
```

When a CASE clause contains multiple tests separated by commas, a logical OR is performed. That is, if any one (or more) of the tests is TRUE, the entire clause is deemed to be TRUE.

Use EXIT SELECT to jump out of a SELECT block prematurely.

PowerBASIC now offers four optional modifiers to provide highly optimized code generation for specific circumstances. By default, numeric expressions are evaluated either as

values (to offer the widest range of compatibility for any possible circumstance) or as (for example, if PowerBASIC can establish that all case clauses are integer class values, etc). Further, string expressions are evaluated dynamically to allow virtually any data. However, if limits on the type *and* range of the data used for CASE comparison are restricted, performance can be dramatically enhanced with the LONG, CONST, CONST$, or CONST$$ clauses.

AS LONG — In this case, the controlling expression and the CASE expressions must evaluate in the range of a Long-integer. Each of these expressions are calculated dynamically, so all of the normal operators are still available. Performance is enhanced by the integral class of code generation, rather than floating-point. For example, DWORD values are treated as Long-integer values, so &H0FFFFFFFF??? and -1& would be considered equal values. This can help eliminate the need to use functions such as BITS when performing comparisons between signed and unsigned values.

AS CONST — In this case, the controlling expression must evaluate in the range of a Long-integer. However, each of the case values must be strictly specified by a numeric literal (or numeric equate) in the range of a Long-integer. Multiple case values may be given (CASE 2,3,7), but operators and ranges of values are not allowed. CASE ELSE is permitted. Performance is enhanced by the internal creation of a vector jump table, one entry for each number from the smallest to the largest case value.

While this form of the structure offers the utmost performance possible, the execution speed must be carefully weighed against the increased program size, particularly when using sparse case values. For example, with just two CASE values of 2 and 1000, the generated jump table would need 999 table entries (3996 bytes in size). The largest allowed jump table for this form is approximately 3200 entries (12K bytes). If exceeded, an Error 402 is generated ("Statement too long/complex").

AS CONST$ — In this case, the controlling expression must evaluate to an ANSI string of length zero through 255 bytes. However, each of the case values must be strictly specified by a string literal (a quoted ANSI string, or an ANSI string equate). Multiple case values may be given (CASE "a","Bob",$value), but operators and ranges of values are not allowed. Performance is enhanced by the internal creation of a vectored scan table, eight bytes for each case value specified.

AS CONST$$ — In this case, the controlling expression must evaluate to a WIDE (Unicode) string of length zero through 127 characters. However, each of the case values must be strictly specified by a string literal (a quoted wide string, or a wide string equate). Multiple case values may be given (CASE "a"$$,"Bob"$$,$$value), but operators and ranges of values are not allowed. Performance is enhanced by the internal creation of a vectored scan table, eight bytes for each case value specified.

See also — CHOOSE, CHOOSE&, CHOOSE$, EXIT SELECT, IF, IF block, IIF, IIF&, IIF$, MAX, MAX&, MAX$, MIN, MIN&, MIN$, ON GOTO, ON GOSUB, SWITCH, SWITCH&, SWITCH$

Example

```
DIM Dwrd AS DWORD
DIM Lint AS LONG

Dwrd = &H0FFFFFFFF???
Lint = -1&

SELECT CASE Lint
  CASE Dwrd
    a$ = "A Match!"
  CASE ELSE
    a$ = "*No Match"
END SELECT

SELECT CASE AS LONG Lint
  CASE Dwrd
    a$ = "*A Match!"
  CASE ELSE
    a$ = "No Match"
```

```
END SELECT

SELECT CASE AS CONST Dwrd
  CASE -1&
    a$ = "*A Match!"
  CASE 0
    a$ = "No Match"
END SELECT
```

Result

```
*No Match
*A Match!
*A Match!
```

SETATTR statement

SETATTR statement

Purpose Set the file system attribute(s) of a disk file or directory.

Syntax **SETATTR *filespec$, attribute***

Remarks *filespec$* specifies a filename (optionally including a drive letter and directory path). *attribute* is a standard operating system attribute code:

Attribute	Description	Equate
0	Normal	%NORMAL
1	Read-only	%READONLY
2	Hidden	%HIDDEN
4	System	%SYSTEM
32	Archived	%ARCHIVE

The attribute code of a given file or directory may be constructed from a combination of individual attribute values. For example, if you use an *attribute* of 0, *filespec$* will be a regular file: not read-only, not hidden, not system, and not archived.

See also DIR$, FILEATTR, GETATTR

Example

```
Files$ = "MYTEST.DAT"
SETATTR Files$, %HIDDEN + %SYSTEM
IF ISFALSE ERR THEN a$ = Files$ + " has been hidden!"
```

SETEOF statement

SETEOF statement

Purpose Truncate or extend an open file to its current file pointer (read/write) position.

Syntax **SETEOF [#] *filenum&***

Remarks SETEOF will truncate or extend an open file to its current file pointer (read/write) position, which may be set explicitly with the SEEK statement.

Unlike 16-bit Windows and DOS BASIC, Win32 will not truncate a file if you simply write an empty string to it, so the SETEOF statement is provided to cater for this need.

See also CLOSE, FILEATTR, FLUSH, OPEN, SEEK function, SEEK statement

Example

```
FUNCTION PBMAIN
  OPEN "Temp.dat" FOR BINARY AS #1 BASE = 1
  A$ = SPACE$(50)
  PUT$ #1, A$
  ' File is now 50 bytes
  SEEK #1, 15
  ' Move to the 15th byte and truncate there
```

```
  SETEOF #1
  ' File is now 14 bytes
  CLOSE #1
END FUNCTION
```

SGN function

SGN function

Purpose Return the sign of a numeric expression.

Syntax `y = SGN(numeric_expression)`

Remarks If *numeric_expression* is positive, SGN returns 1. If *numeric_expression* is zero, SGN returns 0. If *numeric_expression* is negative, SGN returns -1.

In conjunction with the ON GOTO and ON GOSUB statements, SGN can produce a FORTRAN-like three-way branch:

```
ON SGN(balance) + 2 GOTO InTheRed, BreakingEven, InTheMoney
```

See also ABS, IF, ON GOSUB, ON GOTO, SELECT

Example

```
' ON SGN value, GOSUB appropriate subroutine
ON SGN (value) + 2 GOSUB Minus, Zero, Plus
' more code here
Minus:
x$ = "The product is negative" : RETURN
Zero:
x$ = "The product is zero"     : RETURN
Plus:
x$ = "The product is positive" : RETURN
```

SHELL function

SHELL function

Purpose Run an executable program asynchronously (as a separate process), while execution of the original application continues uninterrupted.

Syntax `ProcessId??? = SHELL([HANDLES,] CmdString [, WndStyle])`

Remarks The SHELL function has the following parts:

CmdString The name of the program to execute ("child process"), along with and any required arguments or command-line switches.

WndStyle A number corresponding to the style of the window in which the child process is to be executed. If *WndStyle* is omitted, the program is opened *normal with focus*, the same as *WndStyle* = 1.

The following table identifies the values for *WndStyle* and the resulting style of window:

WndStyle	Window style
0	Hide window
1	Normal with focus (default)
2	Minimized with focus
3	Maximized with focus
4	Normal without focus
6	Minimized without focus

SHELL returns the *process id* of the child process. The process id is a 32-bit LONG or DWORD value that identifies the child process, if it's a 32-bit or 64-bit process. If the process id is zero, the child process is not a 32-bit or 64-bit process, or an error occurred.

Use ERR to detect the success of the SHELL function. The HANDLES option allows the child process to inherit the file handles opened by your program. This affects only Windows handles, not PowerBASIC file identifiers. It is an advanced option, for those who know it works and why they need it.

Restrictions Child processes run asynchronously, or independently of the program that SHELLs. So, the child process is, probably, still running after control returns from SHELL to your program. Also, if your program ends before the child process, the child process will continue to run.

To use internal DOS commands like DIR and COPY, you must run the DOS command processor, passing the DOS command as a parameter. See the example below.

If the program name in *CmdString* does not include an explicit path, Windows will search for the file in the following paths: the directory where the current program is located, the default directory, the 32-bit Windows system directory, the 16-bit Windows system directory, the Windows directory, and any directories listed in the PATH environment variable.

See also ERR, SHELL statement

Example

```
pid??? = SHELL(MyApp$,1)
pid??? = SHELL(ENVIRON$("COMSPEC") + " /C DIR *.* > filename.txt")
```

SHELL statement

SHELL statement

Purpose Run an executable program synchronously. The SHELLing thread of the calling program is suspended until the SHELLed program ends.

Syntax **SHELL [HANDLES,]** ***CmdString*** **[,** ***WndStyle*****, EXIT TO** ***exitcode&*****]**

Remarks The SHELL statement has the following parts:

HANDLES This option, if present, allows the child process to inherit (and access) the Windows file handles of all open files in the parent process. These are not PowerBASIC file numbers, but system file handles and you must use OPEN HANDLE to access them.

CmdString The name of the program to execute ("child process"), along with and any required arguments or command-line switches.

WndStyle A number corresponding to the style of the window in which the program is to be executed. If *WndStyle* is omitted, the program is opened *normal with focus*, the same as *WndStyle* = 1.

The following table identifies the values for *WndStyle* and the resulting style of window:

WndStyle	Window style
0	Hide window
1	Normal with focus (default)
2	Minimized with focus
3	Maximized with focus
4	Normal without focus
6	Minimized without focus

Use ERR to detect the success of the SHELL function. The HANDLES option allows the child process to inherit the file handles opened by your program. This affects only Windows handles, not PowerBASIC file identifiers. It is an advanced option, for those who know it works and why they need it.

exitcode& The exit code of the child process (the value returned by the WinMain function) is assigned to the long integer variable specified by *exitcode&*.

Restrictions The SHELL statement executes the child process synchronously. That is, SHELL will not return control to your program until the child program finishes.

To use internal DOS commands like DIR and COPY, you must run the DOS command processor, passing the DOS command as a parameter. See the example below.

If the program name in *CmdString* does not include an explicit path, Windows will search for the file in the following paths: the directory where the current program is located, the default directory, the 32-bit Windows system directory, the 16-bit Windows system directory, the Windows directory, and any directories listed in the PATH environment variable.

If the SHELL statement is not executed successfully, an appropriate error is generated. The ERR function can be used to detect it.

See also ERR, SHELL function

Example

```
SHELL MyApp$,1, EXIT TO exitvar&
SHELL ENVIRON$("COMSPEC") + " /C DIR *.* > filename.txt"
```

SHIFT statement

SHIFT statement

Purpose Shift the bits in an variable.

Syntax **SHIFT [SIGNED] {LEFT | RIGHT}** ***ivar, countexpr***

Remarks *ivar* must be one of the integral-class variable types: Byte, Word, Integer, Double-word, Long-integer, or Quad-integer. *countexpr* is an integral-class expression specifying the number of bits by which to shift *ivar*.

SHIFT shifts all the bits in *ivar* without special regard to the sign bit of a signed integral-class variable.

SIGNED — The SIGNED option shifts everything, but does not allow the sign (positive or negative) of the value to change.

LEFT | RIGHT — The LEFT or RIGHT option determines the direction of the bit SHIFT operation. SHIFT LEFT shifts the bits toward the high-order end of *ivar*, and SHIFT RIGHT shifts bits toward the low-order end of *ivar*.

See also AND, BIT function, BIT statement, BITS functions, NOT, OR, ROTATE, XOR

Example

```
DIM i AS BYTE
n = 221
SHIFT LEFT n, 1          ' binary 1 1 0 1 1 1 0 1
' n = 186                ' binary 1 0 1 1 1 0 1 0

n = 221
SHIFT RIGHT n, 1         ' binary 1 1 0 1 1 1 0 1
' n = 110                ' binary 0 1 1 0 1 1 1 0

n = 221
SHIFT SIGNED RIGHT n, 1  ' binary 1 1 0 1 1 1 0 1
n = 238                  ' binary 1 1 1 0 1 1 1 0
```

SHRINK$ function

Keyword Template

Purpose

Syntax

Remarks
See also
Example

SHRINK$ function New!

Purpose Shrink a

to use a consistent single character delimiter.

Syntax

```
NewString$ = SHRINK$(OldString$)
NewString$ = SHRINK$(OldString$, Mask$)
```

Remarks The purpose of this function is to create a string with consecutive data items (words) separated by a consistent single character. This makes it very straightforward to parse the results as needed.

In the first form, all leading spaces and trailing spaces are removed entirely. All occurrences of two or more spaces are changed to a single space. Therefore, the new string returned consists of zero or more words, each separated by a single space character.

In the second form, *Mask$* defines one or more delimiter characters to shrink. All leading and trailing mask characters are removed entirely. All occurrences of one or more mask characters are replaced with the first character of *Mask$*. Therefore, the new string returned consists of zero or more words, each separated by the character found in the first position of *Mask$*.

WhiteSpace is generally defined as the four common non-printing characters: Space, Tab, Carriage-Return, and Line-Feed. This is pre-defined in PowerBASIC as string equates for your convenience. The ANSI version is named $WHITESPACE, while the WIDE version is $$WHITESPACE. This equate is particularly well suited to be used as *Mask$* in this function.

See also CLIP$, INSTR, LTRIM$, REMOVE$, REPLACE, RTRIM$, TRIM$, UNWRAP$

SIN function

SIN function

Purpose Return the sine of its argument.

Syntax

```
y = SIN(numeric_expression)
```

Remarks *numeric_expression* is an angle specified in radians. SIN returns an Extended-precision value between -1 and +1.

To convert radians to degrees, multiply by 57.29577951308232##. To convert degrees to radians, multiply by 0.0174532925199433##. For more information on radians, see the ATN function.

The Inverse Sine (ARCSIN) of a value can be calculated as follows:

```
ArcSin = ATN(Value / SQR(1 - Value * Value))
```

The Hyperbolic Sine (SINH) of a value can also be calculated:

```
SinH = (EXP(Value) - EXP(-Value)) / 2
```

The Inverse Hyperbolic Sine (ARCSINH) of a value can also be calculated:

```
ArcSinH = LOG(Value + SQR(Value * Value + 1))

' Useful Macro functions
MACRO Pi = 3.141592653589793##
MACRO DegreesToRadians(dpDegrees) = (dpDegrees * 0.0174532925199433##)
```

```
MACRO RadiansToDegrees(dpRadians) = (dpRadians * 57.29577951308232##)
```

See also ATN, COS, TAN

Example

```
pi## = 3.141592653589793##
FOR I& = 0 TO 360 STEP 45
  x$ = "The Sine of " + FORMAT$(I&,"* 0") + _
    " degrees =" + FORMAT$(SIN(pi## / 180 * _
    I&),"* 0.00")
NEXT I&
```

Result

```
The Sine of   0 degrees =  0.00
The Sine of  45 degrees =  0.71
The Sine of  90 degrees =  1.00
The Sine of 135 degrees =  0.71
The Sine of 180 degrees =  0.00
The Sine of 225 degrees = -0.71
The Sine of 270 degrees = -1.00
The Sine of 315 degrees = -0.71
The Sine of 360 degrees =  0.00
```

SIZEOF function

SIZEOF function

Purpose Return the total or physical length of any PowerBASIC variable.

Syntax ***x&*** **= SIZEOF(*target*)**

Remarks Particularly useful for determining the maximum length of a fixed-length string, nul-terminated string, or User-Defined Type. It provides similar functionality to LEN, which returns the current length of a data item.

target can be the name of any variable type (fixed-length string, nul-terminated string, User-Defined Type (UDT) variable or definition, etc).

When measuring the size of a padded (aligned) UDT variable or definition with the SIZEOF (or LEN) statement, the measured length includes any padding that was added to the structure. For example, the following UDT structure:

```
TYPE LengthTestType DWORD
  a AS INTEGER
END TYPE
' more code here
DIM abc AS LengthTestType
x& = SIZEOF(abc) ' or use SIZEOF(LengthTestType)
```

Returns a length of 4 bytes in *x&*, since the UDT was padded with 2 additional bytes to enforce DWORD alignment. Note that the SIZEOF of individual UDT members returns the true size of the member without regard to padding or alignment. In the previous example, SIZEOF(abc.a) returns 2.

When used on a dynamic (variable length) string, SIZEOF returns 4, which is the size of the string handle. To obtain the length of the string data in the dynamic string, use the LEN function. SIZEOF also returns 4 for pointer variables, since a pointer is always stored as a DWORD.

Pointers

When used with a dereferenced pointer (i.e., SIZEOF(@p), SIZEOF returns the size of the pointer target variable type, as defined in the DIM *x* AS *y* PTR [* *pSize*] statement.

For example, with a dynamic string pointer, SIZEOF returns 4. If the pointer target is a fixed-length string, UDT, Union, or nul-terminated string, SIZEOF returns the size of the target data structure. However, if the pointer is declared to reference an nul-terminated with no specific target size (i.e., DIM *a* AS STRINGZ PTR), SIZEOF returns 0.

Likewise, if SIZEOF is used on a

STRINGZ string that does not have an explicit length specification, SIZEOF will also return 0. For example:

```
SUB ProcessData(BYREF szText AS STRINGZ)
  ' Within this Sub, SIZEOF(szText) will return 0 because there is no
explicit length specification
```

See also CHRBYTES, DIM, LEN

Example

```
DIM Strval AS STRINGZ * 10
Strval = "test"
' SIZEOF(Strval) = 10, LEN(Strval) = 4

DIM Intval AS QUAD
Intval = 1
' SIZEOF(Intval) = 8, LEN(Strval) = 8

DIM CustName AS STRING
CustName = "Fred Dagg"
' SIZEOF(CustName) = 4, LEN(CustName) = 9

UNION Arrs
  m1(1 TO 1024) AS BYTE
END UNION
DIM p1 AS STRING PTR
DIM p2 AS STRING PTR * 1024
DIM p3 AS Arrs PTR
DIM p4 AS STRINGZ PTR
DIM p5 AS STRINGZ PTR * 64
' Results of SIZEOF on these pointers:
' SIZEOF(p1) = 4, SIZEOF(@p1) = 4
' SIZEOF(p2) = 4, SIZEOF(@p2) = 1024
' SIZEOF(p3) = 4, SIZEOF(@p3) = 1024
' SIZEOF(p4) = 4, SIZEOF(@p4) = 0
' SIZEOF(p5) = 4, SIZEOF(@p5) = 64
' SIZEOF(Arrs) = 1024
```

SLEEP statement

SLEEP statement

Purpose Pause the current thread of the application for a specified number of milliseconds (*mSec*), allowing other processes (or threads) to continue.

Syntax `SLEEP m&`

Remarks *m&* is the number of milliseconds (1 millisecond = 1/1000th of a second) to pause the application. Only the current

pauses. If other threads are present, they will continue to execute. During the SLEEP period, all time-slices for the current thread are given to other threads and processes.

If *m&* is zero, the remainder of the current time-slice is relinquished. If there are no other threads of equal priority, execution continues immediately.

The time-slice duration (also known as the Quantum) can vary from version to version of Windows, ranging from 20 mSec to 120 mSec. Therefore, the Quantum can affect the performance of applications when SLEEP 0 is overused. That is, excessive use of SLEEP 0 can cause an application to cede much of its available processor time, causing a significant drop in application performance.

When code is running in a tight loop, it is quite possible to use up 100% of the available

CPU time, so the occasional use of SLEEP 0 within a tight loop is often beneficial to overall performance of the target PC. For example, it may not be necessary to use SLEEP 0 for *every* iteration of a loop, but every second or third instead.

See also THREAD CREATE, TIMER

Example

```
' Pause for 5 seconds
SLEEP 5000

' Release time-slice every 256 iterations
FOR x& = 0 TO &H0FFFFFFFF&
  ' code goes here
  IF x& MOD 256 = 0 THEN SLEEP 0
NEXT x&
```

SPACE$ function

SPACE$ function

Purpose Return a

consisting of a specified number of spaces.

Syntax ***s$*** **= SPACE$(*numeric_expression*)**

Remarks *numeric_expression* is a non-negative expression that specifies how many spaces the function is to return. SPACE$ can be useful for formatting or prefilling strings.

See also BUILD$, CHR$, CSET, CSET$, LSET, NUL$, REPEAT$, RSET, STRING$

Example

```
A$ = SPACE$(1000000) ' fill A$ with 1000000 spaces
```

SPLIT statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

SPLIT statement New!

Purpose Splits a

into two parts.

Syntax **SPLIT [WORD] *MainStr*, *Part1Len* TO *Part1Var*, *Part2Var***

Remarks *MainStr* is separated into two parts, which are then assigned to the two string variables specified by *Part1Var* and *Part2Var*. *Part1Len* is a

expression which specifies the number of characters to be assigned to Part1, while the remaining characters are assigned to Part2.

WORD If the WORD option is included, PowerBASIC guarantees that Part1 will not end on a partial word. This may require that *Part1Len* is adjusted to a smaller value. In that case, *Part2Var* would be assigned these characters to compensate. Depending upon the nature of the operation, it may be necessary to remove leading spaces from *Part2Var*.

See also GRAPHIC SPLIT, LTRIM$, XPRINT SPLIT

SQR function

SQR function

Purpose Return the square root of its argument.

Syntax ***y*** **= SQR(*numeric_expression*)**

Remarks *numeric_expression* must be greater than or equal to zero. SQR calculates square roots using an optimized algorithm. That is, y = SQR(x) takes less time to execute than y = x^0.5.

Attempting to take the square root of a negative number does not produce any run-time errors, but the results of such an operation are undefined.

SQR returns an Extended-precision result.

See also EXP, EXP2, EXP10, LOG, LOG2, LOG10

STATIC statement

STATIC statement

Purpose Declare static variables inside a Sub, Function, Method, or Property. Static variables retain their values as long as the program is running.

Syntax

STATIC *variable*[()] [AS *type*] [, *variable*[()]]
STATIC *variable*[()] [, *variable*[()]] [, ...] AS *type*

Remarks The STATIC statement is valid only inside a procedure. Static variables retain their values even after the procedure ends. A static variable is local to its procedure, and can have the same name as other variables in other parts of the program without conflict.

To declare an array as a static variable, use an empty set of parentheses in the variable list: You can then use the DIM statement to dimension the array.

```
STATIC MyArray%()
STATIC StringArray() AS STRING
```

The STATIC statement may, optionally, accept a list of variables, all of which are defined by the type descriptor keyword that follows them. For example:

```
STATIC aaa, bbb, ccc AS INTEGER
STATIC vptr, aptr() AS LONG PTR
```

Restrictions DEF*type* has no effect on variables defined by a STATIC statement.

See also DIM, GLOBAL, LOCAL, THREADED

Example

```
#COMPILE EXE
#DIM ALL
#INCLUDE "WIN32API.INC"

DECLARE SUB DoMessage ()

FUNCTION PBMAIN
  DIM z%
  FOR z% = 1 TO 5
    DoMessage
  NEXT z%
END FUNCTION

SUB DoMessage ()
```

```
    STATIC x AS INTEGER
    STATIC Message() AS ASCIIZ * 256
    DIM Message(1 TO 5) AS STATIC ASCIIZ * 256

    INCR x       'add one to x
    Message(x) = "X =" + STR$(x)

    #IF %DEF(%PB_CC32)
      PRINT Message(x)
    #ELSE
      MSGBOX Message(x)
    #ENDIF
  END SUB
```

STATUSBAR SET PARTS statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

STATUSBAR statement

Purpose Manipulate a STATUSBAR control. A StatusBar is a horizontal window, typically at the bottom of a dialog client area, which displays various kinds of status information. It can be divided into parts to display multiple items.

Syntax
`STATUSBAR SET PARTS hDlg, id&, x& [,x&...]`
`STATUSBAR SET TEXT hDlg, id&, item&, style&, text$`

hDlg Handle of the dialog that owns the status bar.

id& The control identifier assigned with CONTROL ADD STATUSBAR.

item& Position of data on the STATUSBAR. First item=1, second=2...

style& Style bits which specify the appearance of the status bar.

text$ A string expression passed as a parameter.

Remarks In each of the following samples and descriptions, the STATUSBAR control which is the subject of the statement is identified by the handle of the dialog that owns the STATUSBAR (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD STATUSBAR.

The value *item&* refers to the position of the text data item on the STATUSBAR, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

STATUSBAR SET PARTS *hDlg*, *id&*, *x&* [,*x&*...]

The STATUSBAR control is partitioned into as many as 32 sections, each of which can be used to display some particular status data to the user. The statement contains from 1 to 32 width parameters (*x&*), which specify the pixel or dialog unit size of that section. You can use a very large number for the last parameter to signify that the section should extend all the way to the right side of the window.

```
STATUSBAR SET PARTS hDlg, id&, 50, 50, 9999
```

For example, the above statement would create a status bar with 2 sections of 50 pixels each, and a third section of the remaining width.

STATUSBAR SET TEXT *hDlg*, *id&*, *item&*, *style&*, *text$*

The text for the data item specified by *item&* is replaced with the new text in *text$*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The status bar style value can be the default value of zero (0), or one of the other style values formed as a bitmask:

Zero (0) default	Text with a border to appear lower than the window.
%SBT_NOBORDERS	The text is drawn without any borders.
%SBT_POPOUT	Text with a border to appear higher than the window.

%SBT_NOBORDERS	The text is drawn without any borders.
%SBT_POPOUT	Text with a border to appear higher than the window.

See also Dynamic Dialog Tools, CONTROL ADD STATUSBAR, CONTROL SET FONT

STR$ function

STR$ function

Purpose Return the

representation of a number in printable form.

Syntax `s$ = STR$(numeric_expression [, digits])`

Remarks STR$ returns the string form of a

variable or expression in printable text form. *digits* is an optional expression specifying the maximum total number of digits to appear in the result. If *numeric_expression* is greater than or equal to zero, STR$ adds a leading space character; if *numeric_expression* is less than zero, STR$ adds a leading negation (minus) character.

For example, STR$(14) returns a three-character string, of which the first character is a space, and the second and third are the ASCII characters "1" and "4". LTRIM$ can be used to remove leading space characters.

digits specifies the maximum number of significant digits (1 to 18) desired in the result.

STR$ can also be used to convert numeric values with more than 16 significant digits (i.e., Extended-precision floating-point and Quad-integers) to a printable form. For example:

```
a## = 2.0/3.0
x$ = STR$(a##,18)
```

returns 0.666666666666666667.

The complementary function is VAL, which takes a string argument and returns the numeric equivalent. Thus, *number* = VAL(STR$(*number*)).

An integer-class numeric value may also be converted to a string with the FORMAT$ and USING$ functions; however, FORMAT$ can easily return a string that is free from leading space characters. For example, x$ = FORMAT$(a&).

See also BIN$, FORMAT$, HEX$, LTRIM$, OCT$, ROUND, USING$, VAL

Example

```
x$ = STR$(-1,5)
x$ = STR$(5/3,2)
x$ = STR$(5/3,8)
x$ = STR$(100000## / 3##, 18)
```

Result

```
-1
 1.7
 1.6666667
 33333.3333333333333
```

STRDELETE$ function

STRDELETE$ function

Purpose Delete a specified number of characters from a string expression.

Syntax `s$ = STRDELETE$(string_expression, start&, count&)`

Remarks Returns a

based on copying *string_expression*, but with *count&* characters deleted starting at position *start&*. The first character in the string is position 1, etc.

See also CLIP$, STRINSERT$, STRREVERSE$

Example `a$ = STRDELETE$("PowerBASIC", 4, 2)`

Result `PowBASIC`

STRING$ function

STRING$/STRING$$ function IMPROVED

Purpose Return a

consisting of multiple copies of the specified character.

Syntax

```
s$  = STRING$(Count&, Character%)
s$  = STRING$(Count&, Character$)
s$$ = STRING$$(Count&, Character%)
s$$ = STRING$$(Count&, Character$$)
```

Remarks This function creates a string which consists of multiple copies of a particular character. The STRING$() form creates a string of ANSI (1-byte) characters, or codes in the range of 0 to 255. The STRING$$() form of the function creates a string of WIDE (2-byte) characters, or codes in the range of 0 to 65535.

Generally speaking, PowerBASIC handles ANSI/WIDE conversions for you, automatically and transparently. However, there are just a few functions (CHR$, PEEK$, POKE$, STRING$, etc) which are ambiguous, by definition, and require that the programmer choose the appropriate result type (ANSI or WIDE). Use STRING$ for ANSI results, or use STRING$$ for Unicode results. In the remainder of these remarks, STRING$ is used to represent both STRING$ and STRING$$.

STRING$ with a

argument returns a string of *Count&* copies of the character with the Character Code of *Character%*. STRING$ with a string argument returns a string of *Count&* copies of the first character in *Character$* or *Character$$*.

The following functions all return a string of 8 spaces:

```
A$ = STRING$(8, 32)
A$ = STRING$(8, " ")
A$ = STRING$(8, $SPC)
A$ = SPACE$(8)
A$ = REPEAT$(8, " ")
A$ = REPEAT$(8, $SPC)
```

Use REPEAT$ to make multiple copies of a multiple-character string, and SPACE$ to return a string of space characters.

See also ASC, BUILD$, CHR$, NUL$, REPEAT$, SPACE$

STRING$$ function

STRING$/STRING$$ function IMPROVED

Purpose Return a

consisting of multiple copies of the specified character.

Syntax

```
s$  = STRING$(Count&, Character%)
s$  = STRING$(Count&, Character$)
s$$ = STRING$$(Count&, Character%)
s$$ = STRING$$(Count&, Character$$)
```

Remarks This function creates a string which consists of multiple copies of a particular character. The STRING$() form creates a string of ANSI (1-byte) characters, or codes in the range of 0 to 255. The STRING$$() form of the function creates a string of WIDE (2-byte) characters, or codes in the range of 0 to 65535.

Generally speaking, PowerBASIC handles ANSI/WIDE conversions for you, automatically and transparently. However, there are just a few functions (CHR$, PEEK$, POKE$, STRING$, etc) which are ambiguous, by definition, and require that the programmer choose the appropriate result type (ANSI or WIDE). Use STRING$ for ANSI results, or use STRING$$ for Unicode results. In the remainder of these remarks, STRING$ is used to represent both STRING$ and STRING$$.

STRING$ with a

argument returns a string of *Count&* copies of the character with the Character Code of *Character%*. STRING$ with a string argument returns a string of *Count&* copies of the first character in *Character$* or *Character$$*.

The following functions all return a string of 8 spaces:

```
A$ = STRING$(8, 32)
A$ = STRING$(8, " ")
A$ = STRING$(8, $SPC)
A$ = SPACE$(8)
A$ = REPEAT$(8, " ")
A$ = REPEAT$(8, $SPC)
```

Use REPEAT$ to make multiple copies of a multiple-character string, and SPACE$ to return a string of space characters.

See also ASC, BUILD$, CHR$, NUL$, REPEAT$, SPACE$

STRINSERT$ function

STRINSERT$ function

Purpose Insert a

at a specified position within another string expression.

Syntax `s$ = STRINSERT$(MainStr$, NewStr$, position&)`

Remarks Returns a string consisting of the string expression *MainStr$*, with the string expression *NewStr$* inserted at *position&*. If *position&* is greater than the length of *MainStr$*, *NewStr$* is appended to *MainStr$*. The first character in the string is position 1, etc.

See also BUILD$, CLIP$, CSET, CSET$, LSET, RSET, STRDELETE$, STRREVERSE$, WRAP$

Example `a$ = STRINSERT$("PowerBASIC", "ful", 6)`

Result `PowerfulBASIC`

STRINGBUILDER Object

Keyword Template

Purpose

Syntax

Remarks

See also

Example

STRINGBUILDER Object New!

Purpose

The StringBuilder object offers the ability to concatenate many sections at a very high level of performance. The speed of execution is particularly noticeable when the concatenation is performed in many separate operations over a period of time. If all of the string sections are known and available at once, the use of the BUILD$() function could be a better choice. However, both options offer a very large boost as compared to the standard concatenation operators (& or +). In addition to concatenation, the StringBuilder Class also offers a few additional string operations to assist in building the string.

Remarks

There are two forms of the StringBuilder object, one for ANSI strings, and one for WIDE (Unicode) strings. While they could have been combined into a single hybrid object, that would have added additional overhead not acceptable for PowerBASIC. To concatenate ANSI strings, use the StringBuilderA class and the IStringBuilderA interface. To concatenate WIDE (Unicode) strings, use the StringBuilderW class and the IStringBuilderW interface. The methods and mode of operation are identical for both forms.

If you choose the ANSI form, parameter strings must be ANSI, and result strings will be ANSI. With the WIDE (Unicode) form, parameter strings must be wide, and result strings will be wide. Keep those requirements in mind when reviewing the following method definitions. The Dispatch ID (DispID) for each member method is displayed within angle brackets.

When you create a StringBuilder object, a dynamic string buffer is created to hold the target string. If you know the size of the result string (or even an approximation), it's usually prudent to use the CAPACITY method first, to establish a size at least as large as the final string. If it's not known, PowerBASIC will try to make appropriate decisions for you. Once the object is created, the ADD method is used to append string sections as many times as necessary. Finally, the STRING method is used to extract the combined items.

StringBuilder Methods/Properties

ADD (*PowerString$*) **Method<1>**

The *PowerString$* parameter is appended to the string held in the StringBuilder object. If the internal string buffer overflows, PowerBASIC will automatically extend it to an appropriate size. If a necessary buffer extension fails, an HResult of E_OUTOFMEMORY (&H8007000E) is returned, and an Object Error (99) is generated.

CAPACITY () AS Long **Get Property<2>**

The size of the internal string buffer is retrieved and returned to the caller. The size is the number of characters which can be stored without further expansion.

CAPACITY () = Long **Set Property<2>**

The internal string buffer is expanded to the number of characters specified by the Long

Integer. If the new capacity is smaller or equal to the current capacity, no operation is performed.

CHAR (*Index&*) AS Long **Get Property<3>**

The numeric character code of the character at the position *Index&* is retrieved and returned to the caller. Index&=1 for the first character, 2 for the second, etc. If *Index&* is beyond the current length of the string, the value -1 is returned.

CHAR (*Index&*) = Long **Set Property<3>**

The character at the position *Index&* is changed to that specified by the Long Integer character code. *Index&*=1 for the first character, 2 for the second, etc.

CLEAR **Method<4>**

All data in the object is erased.

DELETE (*Index&, Count&*) **Method<5>**

Count& characters are removed starting at the position given by *Index&*. *Index&*=1 for the first character, 2 for the second, etc.

INSERT (*PowerString$, Index&*) **Method<6>**

The *PowerString$* parameter is inserted in the string starting at the position given by *Index&*. *Index&*=1 for the first character, 2 for the second, etc. If *Index&* is beyond the current length of the string, no operation is performed.

LEN () AS Long **Method<7>**

The number of characters currently stored in the object is returned as a long integer value.

STRING AS String **Method<8>**

The string stored in the object is returned to the caller. This string will contain LEN characters.

See also BUILD$, CHR$, CSET, CSET$, JOIN$, LSET, LSET$, REPEAT$, RSET, RSET$, STRING$, STRINSERT$, WRAP$

STRPTR function

STRPTR function

Purpose Return the 32-bit DWORD address of the memory block used to store the data held by a dynamic (variable length) string.

Syntax ***xPtr* = STRPTR(*StringVar*)**

Remarks *StringVar* is the name of a string variable. STRPTR returns the 32-bit address in memory, where the contents of *StringVar* are stored.

Note that STRPTR differs from VARPTR. When used with a string variable, VARPTR returns the address of the string's *handle*, while STRPTR returns the address of the actual string *data*. Similarly, a STRING POINTER (or STRING PTR) is a pointer to a string handle - this important distinction should be recognized when working with the VARPTR and STRPTR operations.

STRPTR may not be used with fixed-length or nul-terminated strings, because they do not use string handles. Use VARPTR with fixed-length and nul-terminated strings.

When a dynamic string content is changed, the address of the string data will also change, but the string handle will remain in the same location. Therefore, it is important that your code refresh any pointers that target the string data memory locations directly.

See also CODEPTR, POKE$, PEEK$, VARPTR

Example

```
DIM x AS ASCIIZ PTR, A$
A$ = "PowerBASIC"
x = STRPTR(A$)    ' address of the string data
Message$ = A$     ' returns A$
Message$ = @x     ' returns A$ as the target of x
```

```
A$ = "The power of BASIC!"
x = STRPTR(A$)    ' Update string pointer address
Message$ = @x     ' returns the target of x
```

Result As the code above runs, Message$ is assigned the following strings:

```
PowerBASIC
PowerBASIC
The power of BASIC!
```

STRREVERSE$ function

STRREVERSE$ function

Purpose Reverse the contents of a

expression.

Syntax ***s$*** **= STRREVERSE$(*MainStr$*)**

Remarks Reverses the contents of *MainStr$* and returns the result.

See also STRDELETE$, STRINSERT$

Example `a$ = STRREVERSE$("PowerBASIC")`

Result `CISABrewoP`

SUB/END SUB statements

SUB/END SUB statements IMPROVED

Purpose Define a Sub code section.

Syntax

```
SUB ProcName [ALIAS "AliasName"] [(arguments)] <Descriptors>
  [statements]
END SUB
```

Remarks All executable code must reside in a Sub, Function. Method, Property, or FastProc block. Subs may not be nested. That is, you cannot define a code block (Sub, Function, Method, FastProc, Property) inside another code block.

SUB and END SUB define a subroutine-like block of statements called a procedure (or subprogram), which is invoked with the CALL statement, and may be passed parameters by value or by reference. A Sub may also be invoked without the use of the CALL statement. If the CALL word is omitted, the parentheses around the arguments list must also be omitted.

Previous versions of PowerBASIC required that you create an explicit DECLARE statement if you wished to execute a SUB or FUNCTION which did not physically precede the reference to it. This extra work is no longer required, as PowerBASIC resolves all forward references to internal procedures automatically.

DECLARE statements for a Sub/Function imported from a DLL must still precede any reference to the procedure.

ProcName The name of the Sub. *ProcName* must be unique: no other variable, Function, Sub, Method, Property, FastProc or label can share it.

ALIAS String literal that identifies a case-sensitive alternative name for the sub. This lets you export a Sub by a different unique name. This can be useful if you want to abbreviate a long name, provide a more descriptive name, or if the exported name needs to contain characters that are illegal in PowerBASIC. *AliasName* is the routines actual name as it appears in the export table, and *ProcName* is the title that you can use in PowerBASIC. For example:

```
SUB ShortName ALIAS "LongProcName" () EXPORT STATIC
```

The ALIAS clause is very important when exporting procedures. Omitting the ALIAS clause or incorrectly capitalizing the alias name are common causes of "Missing Export" errors. Please refer to the DECLARE topic for more information.

Descriptors

You may optionally add one or more descriptor words (Export, Common, Private, ThreadSafe, Local, Static, BDecl, CDecl, SDecl) to provide specific functionality. They may be added to the SUB as a comma delimited list. You should note that some of them are mutually exclusive.

EXPORT This descriptor identifies a Sub or Function which may be accessed between Dynamic Link Libraries (DLLs), and/or the main executable which links them. If a procedure is not marked EXPORT, it is hidden from these other modules. The EXPORT attribute may be added to a Sub/Function defined elsewhere, by specifying EXPORT in a DECLARE statement. EXPORT can even be added to a Sub/Function in an SLL with a DECLARE in the host module.

COMMON A COMMON Sub/Function is one which may be referenced by and between linked unit modules (Host or SLL). If you DECLARE a Common Sub or Function which is not present in this module, it is presumed to be found in a separate linked module (Host or SLL).

PRIVATE A PRIVATE Sub/Function is one which may only be accessed from within the current PowerBASIC program or library. Even if not specified, this is the default mode of operation.

THREADSAFE With the THREADSAFE option, PowerBASIC automatically establishes a semaphore which allows only one

to execute the Sub/Function at a time. Other callers must wait until the first thread exits the THREADSAFE procedure before they are allowed to begin.

LOCAL This descriptor specifies that all undeclared variables in a sub are LOCAL. This is the default condition if neither LOCAL nor STATIC is specified.

Local variables and arrays variables are automatically deallocated when the procedure terminates. LOCAL scalar variables (except dynamic strings) are stored on the stack, and visible only within the sub.

STATIC This descriptor specifies that all undeclared variables in a sub are STATIC. Static variables retain their values as long as the program is running. They are visible only within the sub.

BDECL Specifies that the declared procedure uses the legacy BASIC/Pascal calling convention. Parameters are pushed on the stack from left to right, and the called procedure is responsible for removing them. BDECL should only be used when necessary to match outside modules.

CDECL Specifies that the declared procedure uses the C calling convention. Parameters are pushed on the stack from right to left, and the calling code is responsible for removing them. CDECL should only be used when necessary to match outside modules.

SDECL This is the default convention, and should be used whenever possible. SDECL (and its synonym STDCALL), specifies the "Standard Calling Convention" for Windows. Parameters are pushed on the stack from right to left, and the called procedure is responsible for removing them.

Passing Parameters

Arguments An optional, comma-delimited sequence of formal parameters. The parameters used in the arguments list serve only to define the Function; they have no relationship to other variables in the calling code with the same name.

Normally, PowerBASIC passes parameters to a Sub either by reference (BYREF) or by value (BYVAL). If you do not need to modify the parameters (true in many cases), you can speed up your calls by passing the parameters by value using the BYVAL keyword.

You can clarify that a parameter is passed by reference by using the optional BYREF keyword.

The type of the parameter is specified either by appending a type-specifier character to the name or by using an AS clause. For example:

```
SUB Test(A AS INTEGER) ' integer passed by reference
SUB Test(A%)           ' integer passed by reference
SUB Test(BYREF A%)     ' integer passed by reference
SUB Test(BYVAL A%)     ' integer passed by value
```

Parameter Restrictions

PowerBASIC compilers have a limit of 32 parameters per Sub. To pass more than 32 parameters to a FUNCTION, construct a User-Defined Type (UDT) and pass the UDT by reference (BYREF) instead.

Pointer Parameters

When a Sub definition specifies either a BYREF parameter or a pointer variable parameter, the calling code may freely pass a BYVAL DWORD or a Pointer instead. Pointer variable parameters must always be declared as BYVAL parameters.

```
' Integer Pointer (passed by value)
SUB Test(BYVAL A AS INTEGER PTR)
  @A = 56
END SUB
```

Additional information on BYVAL/BYREF/BYCOPY parameter passing can be found in the CALL statement topic.

Using OPTIONAL/OPT

SUB statements may specify one or more parameters as optional by preceding the parameter with either the keyword OPTIONAL or OPT. Optional parameters are only allowed with CDECL or SDECL calling conventions, not BDECL.

When a parameter is declared optional, all subsequent parameters in the declaration are optional as well, whether or not they specify an explicit OPTIONAL or OPT directive. The following two lines are equivalent, with both second and third parameters being optional:

```
SUB sABC(a&, OPTIONAL BYVAL b&, OPTIONAL BYVAL c&)
SUB sABC(a&, OPT BYVAL b&, BYVAL c&)
```

VARIANT variables are particularly well suited for use as an optional parameter. If the calling code omits an optional VARIANT parameter, (BYVAL or BYREF), PowerBASIC (and most other compilers) substitute a variant of type VT_ERROR which contains an error value of %DISP_E_PARAMNOTFOUND (&H80020004). In this case, you can check for this value directly, or use the ISMISSING() function to determine whether the parameter was physically passed or not.

When optional parameters (other than a VARIANT) are omitted in the calling code, the stack area normally reserved for those parameters is zero-filled. This allows you to test if an optional parameter was passed or not.

If the parameter is defined as a BYVAL parameter, it will have the value zero. For TYPE or UNION variables passed BYVAL, the compiler will pass a string of binary zeroes of length SIZEOF(*Type*_or_*union_var*).

If the parameter is defined as a BYREF parameter, VARPTR (*varname*) will equal zero; when this is true, any attempt to use *varname* in your code will result in Error #9 (null pointer); failure to detect this error using error-trapping may result in a General Protection Fault or memory corruption. You should use the ISMISSING() function first to determine whether it is safe to access the parameter.

Because the FUNCTION, SUB, FASTPROC, METHOD, or PROPERTY being called does not know how many parameters are being passed at the time it is called, you should pass the number of parameters as one of the required parameters in the list.

Variables within Subs

LOCAL variables are created within the procedure stack frame. If a LOCAL variable exceeds the amount of stack space available, it may become necessary to use a STATIC or GLOBAL variable instead. For example, creating a LOCAL nul-terminated or LOCAL fixed-length string that is very large (say, approaching 1 MB) can trigger a General Protection Fault (GPF) because it may overrun the stack frame.

Procedure definitions and program flow

The position of procedure definitions is mostly immaterial. They are usually grouped together in one region of the source code, but you cannot nest procedure definitions. That is, you cannot define a procedure within another procedure (although a procedure definition can contain calls to other procedures). Unlike subroutines (see GOSUB), program execution cannot accidentally "fall into" a procedure, even if it is located before the PBMAIN or WINMAIN Function in your code. For example:

```
 #COMPILE EXE
SUB DisplayInfo(a$)
  ' Code goes here
END SUB
...
FUNCTION PBMAIN
   ' Main program code goes here
END FUNCTION
```

When this program is executed, the code in DisplayInfo is only executed if the procedure is explicitly called, even though it is located earlier in the source code file. Procedure definitions should be treated like isolated islands of code; do not jump in or out of them with GOTO, GOSUB or RETURN. Within a procedure block, such statements are legal.

See also CALL, DECLARE, EXIT SUB, FASTPROC, FUNCNAME$, FUNCTION/END FUNCTION, GLOBAL, GOSUB, ISMISSING, LOCAL, RETURN, STATIC

Example

```
SUB TestProcedure(I%, L&, S!, D#, E##, A())
  ' Code to process parameters
END SUB           ' end procedure TestProcedure

DIM MyArray(20)   ' declare array of numbers
IntegerVar% = 1
LongInt&    = 2
SinglePre!  = 3
DoublePre#  = 4
MyArray(3)  = 5
CALL TestProcedure(IntegerVar%, LongInt&, SinglePre!, DoublePre#,
IntegerVar%^2, MyArray())
```

SWAP statement

SWAP statement

Purpose Exchange the values of two variables of the same

.

Syntax `SWAP var1, var2`

Remarks var1 and var2 are two variables of the same type. If you try to swap variables of differing types (for example,

and , or Single-precision and Double-precision), a compile-time Error 482 occurs ("Data type mismatch").

SWAP is handy because a simple trading of values in two consecutive assignment statements does not get the job done:

```
a = b
b = a
```

By the time you make the second assignment, variable *a* does not contain the value it used to. To do this without the SWAP statement requires a temporary variable and a third assignment:

```
temp = a
a = b
b = temp
```

SWAP *can* be used to swap the *target* values of pointers. In addition, SWAP can also be used to swap the values of pointers themselves.

SWITCH function

SWITCH function

Purpose

Return one of a series of values based upon a TRUE/FALSE evaluation of a corresponding series of expressions.

Syntax

```
var  = SWITCH(expr1, val1 [[, expr2, val2], ...])
var& = SWITCH&(expr1, val1& [[, expr2, val2&], ...])
var$ = SWITCH$(expr1, val1$ [[, expr2, val2$], ...])
```

Remarks

SWITCH expects values of any

type. SWITCH& expects values optimized for Long-integer type. SWITCH$ expects values of type.

If *expr1* evaluates TRUE, *val1* is returned, if *expr2* evaluates TRUE, *val2* is returned, etc.

Each control expression in the series is evaluated as a typical PowerBASIC Boolean expression, which offers short-circuit expression evaluation as needed. To force a bitwise evaluation of an expression, enclose it in parentheses. The value parameters may be expressions, literals or variables of the appropriate data type for the SWITCH function in use.

SWITCH returns the matching value parameter from the first TRUE evaluation of the control expressions, evaluated from left to right in the list. Therefore, it would be wise to place the most likely selections at the front of the SWITCH list to achieve the utmost efficiency. If no expressions evaluate to TRUE, then zero (0) is returned.

Restrictions

Contrary to the implementation in some other languages, only the chosen value (one of *val1*, *val2*, *val3...)* is evaluated at run-time; the other value parameters are not. This ensures optimum execution speed, as well as the elimination of unanticipated side effects.

CHOOSE, IF, IIF, SELECT

Example

```
' SWITCH with simple expressions
A$ = SWITCH$(x%=1, "Bob", x%=20, "Bruce", x% > 20, "Dan", x% < 1,
"Nobody!")

' SWITCH with complex expressions
FUNCTION z(i&) AS LONG
  INCR i&
  FUNCTION = i&
END FUNCTION

FUNCTION PBMAIN
  x& = -1
  Choice& = SWITCH&(z(x&), 1, z(x&), 2, z(x&), 3)
  ' Choice& will equal 2
END FUNCTION
```

TAB$ function

TAB$ function

Purpose Return a

with embedded TAB ($TAB) characters expanded with spaces to a given tab stop.

Syntax `sResult$ = TAB$(strtotab$, tabstop&)`

Remarks All TAB (CHR$(9) or $TAB) characters in *strtotab$* are replaced with spaces to pad the resulting string to the tab stop position specified in *tabstop&*. *strtotab$* and *tabstop&* may be variables, literals, or expressions.

Restrictions If the tab stop specified in *tabstop&* is less than 1 or greater than 256, the original string is returned unchanged.

See also PARSE$, REPLACE

Example

```
a$ = "Hello" & $TAB & "World" & $TAB & _
  "From PB, Inc."
b$ = TAB$(a$,8)
```

Result `b$ contains "Hello   World   From PB, Inc."`

TAB statement IMPROVED

Purpose A Tab Control is analogous to the dividers in a notebook. It displays one particular page, selecting it from multiple pages, when the user chooses the corresponding tab. The TAB statement is used to manipulate a TAB control.

Syntax

```
TAB DELETE hDlg, ID&, PageNum&
TAB GET COUNT hDlg, ID& TO CountVar&
TAB GET DIALOG hDlg, ID&, PageNum& TO PageDlgVar&
TAB GET IMAGE hDlg, ID&, PageNum& TO ImageVar&
TAB GET PAGE PageDlg TO PageNumVar&
TAB GET SELECT hDlg, ID& TO PageNumVar&
TAB GET TEXT hDlg, ID&, PageNum& TO TextVar$
TAB INSERT PAGE hDlg, ID&, PageNum&, Image&, Text$ [CALL CallBack] TO
PageDlgVar&
TAB RESET hDlg, ID&
TAB SELECT hDlg, ID&, PageNum&
TAB SET IMAGE hDlg, ID&, PageNum&, Image&
TAB SET IMAGELIST hDlg, ID&, hLst
TAB SET TEXT hDlg, ID&, PageNum&, Text$
Function Form:
CountVar&   = TAB(COUNT,  hDlg, ID&)
PageDlgVar& = TAB(DIALOG, hDlg, ID&, PageNum&)
ImageVar&   = TAB(IMAGE,  hDlg, ID&, PageNum&)
```

```
PageNumVar& = TAB(PAGE,   PageDlg&)
PageNumVar& = TAB(SELECT, hDlg, ID&)
TextVar$    = TAB$(TEXT,  hDlg, ID&, PageNum&)
```

hDlg Handle of the dialog that owns the Tab Control.

id& The control identifier assigned with CONTROL ADD TAB.

Remarks In each of the following descriptions, the Tab Control that is the subject of the statement is identified by the handle of the dialog that owns the Tab Control (hDlg), and the unique control ID you gave it upon creation in CONTROL ADD TAB. Whenever a TAB page number or IMAGELIST image number is referenced, it is indexed to one. That is, the first item is 1, the second item is 2, etc. Variations of TAB which return a single value may be written in the optional Function Form, as shown above. These functions may be embedded in an expression of any complexity.

TAB DELETE *hDlg, ID&, PageNum&*

The page specified by the *PageNum&* parameter is deleted from the Tab Control.

TAB GET COUNT *hDlg, id&* TO *CountVar&*

The number of pages in the TAB Control is retrieved, and assigned to the long integer variable specified by *CountVar&*.

TAB GET DIALOG *hDlg, ID&, PageNum&* TO *PageDlgVar&*

The handle of the child dialog attached to a TAB Control page is retrieved and assigned to the variable designated by *PageDlgVar&*. The dialog handle to be returned is determined by the value of the parameter *PageNum&*. If that page/dialog not exist, the value zero is returned.

TAB GET IMAGE *hDlg, ID&, PageNum&* TO *ImageVar&*

The index of the image displayed on the specified TAB page is retrieved, and assigned to the variable specified by *ImageVar&*. If no image is displayed, the value zero (0) is assigned.

TAB GET PAGE *PageDlg* TO *PageNumVar&*

Given the handle of a TAB Page Dialog, the PageNum is retrieved, and assigned to the variable specified by *PageNumVar&*. This may be particularly useful when you process CallBack messages for Tab Page Dialogs. If you also need Parent and ID information, you can use WINDOW GET.

TAB GET SELECT *hDlg, id&* TO *SelectVar&*

The index of the currently selected page in the Tab Control is retrieved, and assigned to the variable specified by *SelectVar&*. If there is no current selection, the value zero (0) is assigned.

TAB GET TEXT *hDlg, ID&, PageNum&* TO *TextVar$*

The text displayed on the specified page tab is retrieved, and assigned to the variable specified by *TextVar$*.

TAB INSERT PAGE *hDlg, ID&, PageNum&, Image&, Text$* [CALL *CallBack*] TO *PageDlgVar&*

A page is added to this TAB Control. The parameter *PageNum&* specifies the position of the page to be inserted. An optional image to be displayed on the tab area is selected from the attached IMAGELIST, based upon the parameter *Image&*. Set *Image&* to 0 if no image is desired. The *Text$* parameter specifies the text to be displayed on the tab area. *CallBack* is the name of a callback procedure to be used for the page dialog. The handle of the newly created dialog is assigned to the variable designated by PageDlgVar&.

TAB RESET *hDlg, id&*

All pages in the specified Tab Control are deleted.

TAB SELECT *hDlg, ID&, PageNum&*

The page specified by the *PageNum&* parameter is chosen as the selected page for the TAB control, and the associated dialog is displayed.

TAB SET IMAGE *hDlg, ID&, PageNum&, Image&*

The image specified by the parameter *Image&* is displayed on the page tab specified by the parameter *PageNum&*.

TAB SET IMAGELIST *hDlg, ID&, hLst*

The IMAGELIST specified by *hLst* is attached to this TAB control. The graphical images contained in the IMAGELIST are displayed on the tabs of this control. The image to be displayed is determined by the specification made in TAB INSERT PAGE or TAB SET IMAGE. When the TAB control is destroyed, any attached IMAGELIST is automatically destroyed.

TAB SET TEXT *hDlg, ID&, PageNum&, Text$*

The text in the parameter *Text$* is displayed on the tab of the page specified by *PageNum&*.

TAB DELETE *hDlg, ID&, PageNum&*

The page specified by the *PageNum&* parameter is deleted from the Tab Control.

TAB GET COUNT *hDlg, id&* TO *CountVar&*

The number of pages in the TAB Control is retrieved, and assigned to the long integer variable specified by *CountVar&*.

TAB GET DIALOG *hDlg, ID&, PageNum&* TO *PageDlgVar&*

The handle of the child dialog attached to a TAB Control page is retrieved and assigned to the variable designated by *PageDlgVar&*. The dialog handle to be returned is determined by the value of the parameter *PageNum&*. If that page/dialog not exist, the value zero is returned.

TAB GET IMAGE *hDlg, ID&, PageNum&* TO *ImageVar&*

The index of the image displayed on the specified TAB page is retrieved, and assigned to the variable specified by *ImageVar&*. If no image is displayed, the value zero (0) is assigned.

TAB GET PAGE *PageDlg* TO *PageNumVar&*

Given the handle of a TAB Page Dialog, the PageNum is retrieved, and assigned to the variable specified by *PageNumVar&*. This may be particularly useful when you process CallBack messages for Tab Page Dialogs. If you also need Parent and ID information, you can use WINDOW GET.

TAB GET SELECT *hDlg, id&* TO *SelectVar&*

The index of the currently selected page in the Tab Control is retrieved, and assigned to the variable specified by *SelectVar&*. If there is no current selection, the value zero (0) is assigned.

TAB GET TEXT *hDlg, ID&, PageNum&* TO *TextVar$*

The text displayed on the specified page tab is retrieved, and assigned to the variable specified by *TextVar$*.

TAB INSERT PAGE *hDlg*, *ID&*, *PageNum&*, *Image&*, *Text$* [CALL *CallBack*] TO *PageDlgVar&*

A page is added to this TAB Control. The parameter *PageNum&* specifies the position of the page to be inserted. An optional image to be displayed on the tab area is selected from the attached IMAGELIST, based upon the parameter *Image&*. Set *Image&* to 0 if no image is desired. The *Text$* parameter specifies the text to be displayed on the tab area. *CallBack* is the name of a callback procedure to be used for the page dialog. The handle of the newly created dialog is assigned to the variable designated by PageDlgVar&.

TAB RESET *hDlg*, *id&*

All pages in the specified Tab Control are deleted.

TAB SELECT *hDlg*, *ID&*, *PageNum&*

The page specified by the *PageNum&* parameter is chosen as the selected page for the TAB control, and the associated dialog is displayed.

TAB SET IMAGE *hDlg*, *ID&*, *PageNum&*, *Image&*

The image specified by the parameter *Image&* is displayed on the page tab specified by the parameter *PageNum&*.

TAB SET IMAGELIST *hDlg*, *ID&*, *hLst*

The IMAGELIST specified by *hLst* is attached to this TAB control. The graphical images contained in the IMAGELIST are displayed on the tabs of this control. The image to be displayed is determined by the specification made in TAB INSERT PAGE or TAB SET IMAGE. When the TAB control is destroyed, any attached IMAGELIST is automatically destroyed.

TAB SET TEXT *hDlg*, *ID&*, *PageNum&*, *Text$*

The text in the parameter *Text$* is displayed on the tab of the page specified by *PageNum&*.

Whenever a TAB page number or IMAGELIST image number is referenced, it is indexed to one. That is, the first item is 1, the second item is 2, etc. Variations of TAB which return a single value may be written in the optional Function Form, as shown above. These functions may be embedded in an expression of any complexity.

TAB DELETE *hDlg, ID&, PageNum&*

The page specified by the *PageNum&* parameter is deleted from the Tab Control.

TAB GET COUNT *hDlg, id&* TO *CountVar&*

The number of pages in the TAB Control is retrieved, and assigned to the long integer variable specified by *CountVar&*.

TAB GET DIALOG *hDlg, ID&, PageNum&* TO *PageDlgVar&*

The handle of the child dialog attached to a TAB Control page is retrieved and assigned to the variable designated by *PageDlgVar&*. The dialog handle to be returned is determined by the value of the parameter *PageNum&*. If that page/dialog not exist, the value zero is returned.

TAB GET IMAGE *hDlg, ID&, PageNum&* TO *ImageVar&*

The index of the image displayed on the specified TAB page is retrieved, and assigned to the variable specified by *ImageVar&*. If no image is displayed, the value zero (0) is assigned.

TAB GET PAGE *PageDlg* TO *PageNumVar&*

Given the handle of a TAB Page Dialog, the PageNum is retrieved, and assigned to the variable specified by *PageNumVar&*. This may be particularly useful when you process CallBack messages for Tab Page Dialogs. If you also need Parent and ID information, you can use WINDOW GET.

TAB GET SELECT *hDlg, id&* TO *SelectVar&*

The index of the currently selected page in the Tab Control is retrieved, and assigned to the variable specified by *SelectVar&*. If there is no current selection, the value zero (0) is assigned.

TAB GET TEXT *hDlg, ID&, PageNum&* TO *TextVar$*

The text displayed on the specified page tab is retrieved, and assigned to the variable specified by *TextVar$*.

TAB INSERT PAGE *hDlg, ID&, PageNum&, Image&, Text$* [CALL *CallBack*] TO *PageDlgVar&*

A page is added to this TAB Control. The parameter *PageNum&* specifies the position of the page to be inserted. An optional image to be displayed on the tab area is selected from the attached IMAGELIST, based upon the parameter *Image&*. Set *Image&* to 0 if no image is desired. The *Text$* parameter specifies the text to be displayed on the tab area. *CallBack* is the name of a callback procedure to be used for the page dialog. The handle of the newly created dialog is assigned to the variable designated by PageDlgVar&.

TAB RESET *hDlg, id&*

All pages in the specified Tab Control are deleted.

TAB SELECT *hDlg, ID&, PageNum&*

The page specified by the *PageNum&* parameter is chosen as the selected page for the TAB control, and the associated dialog is displayed.

TAB SET IMAGE *hDlg, ID&, PageNum&, Image&*

The image specified by the parameter *Image&* is displayed on the page tab specified by the parameter *PageNum&*.

TAB SET IMAGELIST *hDlg, ID&, hLst*

The IMAGELIST specified by *hLst* is attached to this TAB control. The graphical images contained in the IMAGELIST are displayed on the tabs of this control. The image to be displayed is determined by the specification made in TAB INSERT PAGE or TAB SET IMAGE. When the TAB control is destroyed, any attached IMAGELIST is automatically destroyed.

TAB SET TEXT *hDlg, ID&, PageNum&, Text$*

The text in the parameter *Text$* is displayed on the tab of the page specified by *PageNum&*.

TAB statement IMPROVED

Purpose A Tab Control is analogous to the dividers in a notebook. It displays one particular page, selecting it from multiple pages, when the user chooses the corresponding tab. The TAB statement is used to manipulate a TAB control.

Syntax

```
TAB DELETE hDlg, ID&, PageNum&
TAB GET COUNT hDlg, ID& TO CountVar&
TAB GET DIALOG hDlg, ID&, PageNum& TO PageDlgVar&
TAB GET IMAGE hDlg, ID&, PageNum& TO ImageVar&
TAB GET PAGE PageDlg TO PageNumVar&
TAB GET SELECT hDlg, ID& TO PageNumVar&
TAB GET TEXT hDlg, ID&, PageNum& TO TextVar$
TAB INSERT PAGE hDlg, ID&, PageNum&, Image&, Text$ [CALL CallBack] TO
PageDlgVar&
TAB RESET hDlg, ID&
TAB SELECT hDlg, ID&, PageNum&
TAB SET IMAGE hDlg, ID&, PageNum&, Image&
TAB SET IMAGELIST hDlg, ID&, hLst
TAB SET TEXT hDlg, ID&, PageNum&, Text$
```

```
Function Form:
CountVar&    = TAB(COUNT,  hDlg, ID&)
PageDlgVar& = TAB(DIALOG, hDlg, ID&, PageNum&)
ImageVar&    = TAB(IMAGE,  hDlg, ID&, PageNum&)
PageNumVar& = TAB(PAGE,   PageDlg&)
PageNumVar& = TAB(SELECT, hDlg, ID&)
TextVar$     = TAB$(TEXT,  hDlg, ID&, PageNum&)
```

hDlg Handle of the dialog that owns the Tab Control.

id& The control identifier assigned with CONTROL ADD TAB.

Remarks In each of the following descriptions, the Tab Control that is the subject of the statement is identified by the handle of the dialog that owns the Tab Control (hDlg), and the unique control ID you gave it upon creation in CONTROL ADD TAB. Whenever a TAB page number or IMAGELIST image number is referenced, it is indexed to one. That is, the first item is 1, the second item is 2, etc. Variations of TAB which return a single value may be written in the optional Function Form, as shown above. These functions may be embedded in an expression of any complexity.

TAB DELETE *hDlg, ID&, PageNum&*

The page specified by the *PageNum&* parameter is deleted from the Tab Control.

TAB GET COUNT *hDlg, id&* TO *CountVar&*

The number of pages in the TAB Control is retrieved, and assigned to the long integer variable specified by *CountVar&*.

TAB GET DIALOG *hDlg, ID&, PageNum&* TO *PageDlgVar&*

The handle of the child dialog attached to a TAB Control page is retrieved and assigned to the variable designated by *PageDlgVar&*. The dialog handle to be returned is determined by the value of the parameter *PageNum&*. If that page/dialog not exist, the value zero is returned.

TAB GET IMAGE *hDlg, ID&, PageNum&* TO *ImageVar&*

The index of the image displayed on the specified TAB page is retrieved, and assigned to the variable specified by *ImageVar&*. If no image is displayed, the value zero (0) is assigned.

TAB GET PAGE *PageDlg* TO *PageNumVar&*

Given the handle of a TAB Page Dialog, the PageNum is retrieved, and assigned to the variable specified by *PageNumVar&*. This may be particularly useful when you process CallBack messages for Tab Page Dialogs. If you also need Parent and ID information, you can use WINDOW GET.

TAB GET SELECT *hDlg, id&* TO *SelectVar&*

The index of the currently selected page in the Tab Control is retrieved, and assigned to the variable specified by *SelectVar&*. If there is no current selection, the value zero (0) is assigned.

TAB GET TEXT *hDlg, ID&, PageNum&* TO *TextVar$*

The text displayed on the specified page tab is retrieved, and assigned to the variable specified by *TextVar$*.

TAB INSERT PAGE *hDlg, ID&, PageNum&, Image&, Text$* [CALL *CallBack*] TO *PageDlgVar&*

A page is added to this TAB Control. The parameter *PageNum&* specifies the position of the page to be inserted. An optional image to be displayed on the tab area is selected from the attached IMAGELIST, based upon the parameter *Image&*. Set *Image&* to 0 if no image is desired. The *Text$* parameter specifies the text to be displayed on the tab area. *CallBack* is the name of a callback procedure to be used for the page dialog. The handle of the newly created dialog is assigned to the variable designated by PageDlgVar&.

TAB RESET *hDlg, id&*

All pages in the specified Tab Control are deleted.

TAB SELECT *hDlg, ID&, PageNum&*

The page specified by the *PageNum&* parameter is chosen as the selected page for the

TAB control, and the associated dialog is displayed.

TAB SET IMAGE *hDlg, ID&, PageNum&, Image&*

The image specified by the parameter *Image&* is displayed on the page tab specified by the parameter *PageNum&*.

TAB SET IMAGELIST *hDlg, ID&, hLst*

The IMAGELIST specified by *hLst* is attached to this TAB control. The graphical images contained in the IMAGELIST are displayed on the tabs of this control. The image to be displayed is determined by the specification made in TAB INSERT PAGE or TAB SET IMAGE. When the TAB control is destroyed, any attached IMAGELIST is automatically destroyed.

TAB SET TEXT *hDlg, ID&, PageNum&, Text$*

The text in the parameter *Text$* is displayed on the tab of the page specified by *PageNum&*.

```

hDlg Handle of the dialog that owns the Tab Control.

id& The control identifier assigned with CONTROL ADD TAB.

Remarks In each of the following descriptions, the Tab Control that is the subject of the statement is identified by the handle of the dialog that owns the Tab Control (hDlg), and the unique control ID you gave it upon creation in CONTROL ADD TAB. Whenever a TAB page number or IMAGELIST image number is referenced, it is indexed to one. That is, the first item is 1, the second item is 2, etc. Variations of TAB which return a single value may be written in the optional Function Form, as shown above. These functions may be embedded in an expression of any complexity.

TAB DELETE *hDlg*, *ID&*, *PageNum&*

The page specified by the *PageNum&* parameter is deleted from the Tab Control.

TAB GET COUNT *hDlg*, *id&* TO *CountVar&*

The number of pages in the TAB Control is retrieved, and assigned to the long integer variable specified by *CountVar&*.

TAB GET DIALOG *hDlg*, *ID&*, *PageNum&* TO *PageDlgVar&*

The handle of the child dialog attached to a TAB Control page is retrieved and assigned to the variable designated by *PageDlgVar&*. The dialog handle to be returned is determined by the value of the parameter *PageNum&*. If that page/dialog not exist, the value zero is returned.

TAB GET IMAGE *hDlg*, *ID&*, *PageNum&* TO *ImageVar&*

The index of the image displayed on the specified TAB page is retrieved, and assigned to the variable specified by *ImageVar&*. If no image is displayed, the value zero (0) is assigned.

TAB GET PAGE *PageDlg* TO *PageNumVar&*

Given the handle of a TAB Page Dialog, the PageNum is retrieved, and assigned to the variable specified by *PageNumVar&*. This may be particularly useful when you process CallBack messages for Tab Page Dialogs. If you also need Parent and ID information, you can use WINDOW GET.

TAB GET SELECT *hDlg*, *id&* TO *SelectVar&*

The index of the currently selected page in the Tab Control is retrieved, and assigned to the variable specified by *SelectVar&*. If there is no current selection, the value zero (0) is assigned.

TAB GET TEXT *hDlg*, *ID&*, *PageNum&* TO *TextVar$*

The text displayed on the specified page tab is retrieved, and assigned to the variable specified by *TextVar$*.

TAB INSERT PAGE *hDlg*, *ID&*, *PageNum&*, *Image&*, *Text$* [CALL *CallBack*] TO *PageDlgVar&*

A page is added to this TAB Control. The parameter *PageNum&* specifies the position of the page to be inserted. An optional image to be displayed on the tab area is selected from the attached IMAGELIST, based upon the parameter *Image&*. Set *Image&* to 0 if no image is desired. The *Text$* parameter specifies the text to be displayed on the tab area. *CallBack* is the name of a callback procedure to be used for the page dialog. The handle of the newly created dialog is assigned to the variable designated by PageDlgVar&.

TAB RESET *hDlg*, *id&*

All pages in the specified Tab Control are deleted.

TAB SELECT *hDlg*, *ID&*, *PageNum&*

The page specified by the *PageNum&* parameter is chosen as the selected page for the TAB control, and the associated dialog is displayed.

TAB SET IMAGE *hDlg*, *ID&*, *PageNum&*, *Image&*

The image specified by the parameter *Image&* is displayed on the page tab specified by the parameter *PageNum&*.

TAB SET IMAGELIST *hDlg*, *ID&*, *hLst*

The IMAGELIST specified by *hLst* is attached to this TAB control. The graphical images contained in the IMAGELIST are displayed on the tabs of this control. The image to be displayed is determined by the specification made in TAB INSERT PAGE or TAB SET IMAGE. When the TAB control is destroyed, any attached IMAGELIST is automatically destroyed.

TAB SET TEXT *hDlg*, *ID&*, *PageNum&*, *Text$*

The text in the parameter *Text$* is displayed on the tab of the page specified by *PageNum&*.

TAB GET IMAGE hDlg, ID&, PageNum& TO ImageVar&
TAB GET PAGE PageDlg TO PageNumVar&
TAB GET SELECT hDlg, ID& TO PageNumVar&
TAB GET TEXT hDlg, ID&, PageNum& TO TextVar$
TAB INSERT PAGE hDlg, ID&, PageNum&, Image&, Text$ [CALL CallBack] TO
PageDlgVar&
TAB RESET hDlg, ID&
TAB SELECT hDlg, ID&, PageNum&
TAB SET IMAGE hDlg, ID&, PageNum&, Image&
TAB SET IMAGELIST hDlg, ID&, hLst
TAB SET TEXT hDlg, ID&, PageNum&, Text$
```

```
Function Form:
CountVar&    = TAB(COUNT,  hDlg, ID&)
PageDlgVar& = TAB(DIALOG, hDlg, ID&, PageNum&)
ImageVar&    = TAB(IMAGE,  hDlg, ID&, PageNum&)
PageNumVar& = TAB(PAGE,   PageDlg&)
PageNumVar& = TAB(SELECT, hDlg, ID&)
TextVar$     = TAB$(TEXT,  hDlg, ID&, PageNum&)
```

hDlg — Handle of the dialog that owns the Tab Control.

id& — The control identifier assigned with CONTROL ADD TAB.

Remarks

In each of the following descriptions, the Tab Control that is the subject of the statement is identified by the handle of the dialog that owns the Tab Control (hDlg), and the unique control ID you gave it upon creation in CONTROL ADD TAB. Whenever a TAB page number or IMAGELIST image number is referenced, it is indexed to one. That is, the first item is 1, the second item is 2, etc. Variations of TAB which return a single value may be written in the optional Function Form, as shown above. These functions may be embedded in an expression of any complexity.

TAB DELETE *hDlg, ID&, PageNum&*

The page specified by the *PageNum&* parameter is deleted from the Tab Control.

TAB GET COUNT *hDlg, id&* TO *CountVar&*

The number of pages in the TAB Control is retrieved, and assigned to the long integer variable specified by *CountVar&*.

TAB GET DIALOG *hDlg, ID&, PageNum&* TO *PageDlgVar&*

The handle of the child dialog attached to a TAB Control page is retrieved and assigned to the variable designated by *PageDlgVar&*. The dialog handle to be returned is determined by the value of the parameter *PageNum&*. If that page/dialog not exist, the value zero is returned.

TAB GET IMAGE *hDlg*, *ID&*, *PageNum&* TO *ImageVar&*

The index of the image displayed on the specified TAB page is retrieved, and assigned to the variable specified by *ImageVar&*. If no image is displayed, the value zero (0) is assigned.

TAB GET PAGE *PageDlg* TO *PageNumVar&*

Given the handle of a TAB Page Dialog, the PageNum is retrieved, and assigned to the variable specified by *PageNumVar&*. This may be particularly useful when you process CallBack messages for Tab Page Dialogs. If you also need Parent and ID information, you can use WINDOW GET.

TAB GET SELECT *hDlg*, *id&* TO *SelectVar&*

The index of the currently selected page in the Tab Control is retrieved, and assigned to the variable specified by *SelectVar&*. If there is no current selection, the value zero (0) is assigned.

TAB GET TEXT *hDlg*, *ID&*, *PageNum&* TO *TextVar$*

The text displayed on the specified page tab is retrieved, and assigned to the variable specified by *TextVar$*.

TAB INSERT PAGE *hDlg*, *ID&*, *PageNum&*, *Image&*, *Text$* [CALL *CallBack*] TO *PageDlgVar&*

A page is added to this TAB Control. The parameter *PageNum&* specifies the position of the page to be inserted. An optional image to be displayed on the tab area is selected from the attached IMAGELIST, based upon the parameter *Image&*. Set *Image&* to 0 if no image is desired. The *Text$* parameter specifies the text to be displayed on the tab area. *CallBack* is the name of a callback procedure to be used for the page dialog. The handle of the newly created dialog is assigned to the variable designated by PageDlgVar&.

TAB RESET *hDlg*, *id&*

All pages in the specified Tab Control are deleted.

TAB SELECT *hDlg*, *ID&*, *PageNum&*

The page specified by the *PageNum&* parameter is chosen as the selected page for the TAB control, and the associated dialog is displayed.

TAB SET IMAGE *hDlg*, *ID&*, *PageNum&*, *Image&*

The image specified by the parameter *Image&* is displayed on the page tab specified by the parameter *PageNum&*.

TAB SET IMAGELIST *hDlg*, *ID&*, *hLst*

The IMAGELIST specified by *hLst* is attached to this TAB control. The graphical images contained in the IMAGELIST are displayed on the tabs of this control. The image to be displayed is determined by the specification made in TAB INSERT PAGE or TAB SET IMAGE. When the TAB control is destroyed, any attached IMAGELIST is automatically destroyed.

TAB SET TEXT *hDlg*, *ID&*, *PageNum&*, *Text$*

The text in the parameter *Text$* is displayed on the tab of the page specified by *PageNum&*.

Example

TAB statement IMPROVED

Purpose

A Tab Control is analogous to the dividers in a notebook. It displays one particular page, selecting it from multiple pages, when the user chooses the corresponding tab. The TAB statement is used to manipulate a TAB control.

Syntax

```
TAB DELETE hDlg, ID&, PageNum&
TAB GET COUNT hDlg, ID& TO CountVar&
TAB GET DIALOG hDlg, ID&, PageNum& TO PageDlgVar&
TAB GET IMAGE hDlg, ID&, PageNum& TO ImageVar&
TAB GET PAGE PageDlg TO PageNumVar&
TAB GET SELECT hDlg, ID& TO PageNumVar&
TAB GET TEXT hDlg, ID&, PageNum& TO TextVar$
TAB INSERT PAGE hDlg, ID&, PageNum&, Image&, Text$ [CALL CallBack] TO
PageDlgVar&
TAB RESET hDlg, ID&
TAB SELECT hDlg, ID&, PageNum&
TAB SET IMAGE hDlg, ID&, PageNum&, Image&
TAB SET IMAGELIST hDlg, ID&, hLst
TAB SET TEXT hDlg, ID&, PageNum&, Text$
```

```
Function Form:
CountVar&    = TAB(COUNT,  hDlg, ID&)
PageDlgVar& = TAB(DIALOG, hDlg, ID&, PageNum&)
ImageVar&    = TAB(IMAGE,  hDlg, ID&, PageNum&)
PageNumVar& = TAB(PAGE,   PageDlg&)
PageNumVar& = TAB(SELECT, hDlg, ID&)
TextVar$     = TAB$(TEXT,  hDlg, ID&, PageNum&)
```

hDlg

Handle of the dialog that owns the Tab Control.

id&

The control identifier assigned with CONTROL ADD TAB.

Remarks

In each of the following descriptions, the Tab Control that is the subject of the statement is identified by the handle of the dialog that owns the Tab Control (hDlg), and the unique control ID you gave it upon creation in CONTROL ADD TAB. Whenever a TAB page number or IMAGELIST image number is referenced, it is indexed to one. That is, the first item is 1, the second item is 2, etc. Variations of TAB which return a single value may be written in the optional Function Form, as shown above. These functions may be embedded in an expression of any complexity.

TAB DELETE *hDlg*, *ID&*, *PageNum&*

The page specified by the *PageNum&* parameter is deleted from the Tab Control.

TAB GET COUNT *hDlg*, *id&* TO *CountVar&*

The number of pages in the TAB Control is retrieved, and assigned to the long integer variable specified by *CountVar&*.

TAB GET DIALOG *hDlg, ID&, PageNum&* TO *PageDlgVar&*

The handle of the child dialog attached to a TAB Control page is retrieved and assigned to the variable designated by *PageDlgVar&*. The dialog handle to be returned is determined by the value of the parameter *PageNum&*. If that page/dialog not exist, the value zero is returned.

TAB GET IMAGE *hDlg, ID&, PageNum&* TO *ImageVar&*

The index of the image displayed on the specified TAB page is retrieved, and assigned to the variable specified by *ImageVar&*. If no image is displayed, the value zero (0) is assigned.

TAB GET PAGE *PageDlg* TO *PageNumVar&*

Given the handle of a TAB Page Dialog, the PageNum is retrieved, and assigned to the variable specified by *PageNumVar&*. This may be particularly useful when you process CallBack messages for Tab Page Dialogs. If you also need Parent and ID information, you can use WINDOW GET.

TAB GET SELECT *hDlg, id&* TO *SelectVar&*

The index of the currently selected page in the Tab Control is retrieved, and assigned to the variable specified by *SelectVar&*. If there is no current selection, the value zero (0) is assigned.

TAB GET TEXT *hDlg, ID&, PageNum&* TO *TextVar$*

The text displayed on the specified page tab is retrieved, and assigned to the variable specified by *TextVar$*.

TAB INSERT PAGE *hDlg, ID&, PageNum&, Image&, Text$* [CALL *CallBack*] TO *PageDlgVar&*

A page is added to this TAB Control. The parameter *PageNum&* specifies the position of the page to be inserted. An optional image to be displayed on the tab area is selected from the attached IMAGELIST, based upon the parameter *Image&*. Set *Image&* to 0 if no image is desired. The *Text$* parameter specifies the text to be displayed on the tab area. *CallBack* is the name of a callback procedure to be used for the page dialog. The handle of the newly created dialog is assigned to the variable designated by PageDlgVar&.

TAB RESET *hDlg, id&*

All pages in the specified Tab Control are deleted.

TAB SELECT *hDlg, ID&, PageNum&*

The page specified by the *PageNum&* parameter is chosen as the selected page for the TAB control, and the associated dialog is displayed.

TAB SET IMAGE *hDlg, ID&, PageNum&, Image&*

The image specified by the parameter *Image&* is displayed on the page tab specified by the parameter *PageNum&*.

TAB SET IMAGELIST *hDlg, ID&, hLst*

The IMAGELIST specified by *hLst* is attached to this TAB control. The graphical images contained in the IMAGELIST are displayed on the tabs of this control. The image to be displayed is determined by the specification made in TAB INSERT PAGE or TAB SET

IMAGE. When the TAB control is destroyed, any attached IMAGELIST is automatically destroyed.

TAB SET TEXT *hDlg, ID&, PageNum&, Text$*

The text in the parameter *Text$* is displayed on the tab of the page specified by *PageNum&*.

See also Dynamic Dialog Tools, CONTROL ADD TAB, CONTROL SET FONT, IMAGELIST

TALLY function

TALLY function

Purpose Count the number of occurrences of specified characters or strings within a

.

Syntax `x& = TALLY(MainString, [ANY] MatchString)`

Remarks *MainString* is the string expression in which to count characters. *MatchString* is the string expression to count all occurrences of. If *MatchString* is not present in *MainString*, zero is returned. When a match is found, the scan for the next match begins at the position immediately following the prior match.

ANY If the ANY keyword is included, *MatchString* specifies a list of single characters to be searched for individually: a match on any one of which will cause the count to be incremented for each occurrence of that character. Note that repeated characters in *MatchString* will not increase the tally. For example:

```
X = TALLY("ABCD", ANY "BDB") ' returns 2, not 3
```

Restrictions TALLY is case-sensitive, so be wary of capitalization.

See also INSTR, JOIN$, LCASE$, LTRIM$, MID$, PARSE, PARSE$, PARSECOUNT, REMOVE$, REPLACE, RIGHT$, RTRIM$, TRIM$, UCASE$, VERIFY

Example

```
' Returns 1, counting the string "bac"
x& = TALLY("abacadabra", "bac")

'returns 8, counting all "b", "a", and "c" characters
x& = TALLY("abacadabra", ANY "bac")
```

TAN function

TAN function

Purpose Return the tangent of its argument.

Syntax `y = TAN(numeric_expression)`

Remarks *numeric_expression* is an angle specified in radians. To convert radians to degrees, multiply by 57.29577951308232##. To convert degrees to radians, multiply by 0.0174532925199433##. For more information on radians, see ATN.

TAN returns an Extended-precision result.

TAN is approximated with the expression:

```
TAN = SIN(Value) / COS(Value)
```

The Inverse Tangent (ARCTAN) of a value can be easily calculated with the ATN function.

The Hyperbolic Tangent (TANH) of a value can be calculated:

```
TanH = (EXP(2 * Value) - 1) / (EXP(2 * Value) + 1)
```

The Inverse Hyperbolic Tangent (ARCTANH) of a value can be calculated:

```
ArcTanH = LOG((1 + Value) / (1 - Value)) / 2

' Useful Macro functions
MACRO Pi = 3.141592653589793##
MACRO DegreesToRadians(dpDegrees) = (dpDegrees * 0.0174532925199433##)
MACRO RadiansToDegrees(dpRadians) = (dpRadians * 57.29577951308232##)
```

See also ATN, COS, SIN

Example

```
pi# = 3.141592653589793##
FOR I& = 5 TO 45 STEP 5
  x$ = "The Tangent of " + FORMAT$(I&,"* ") + _
    " degrees = " + FORMAT$(TAN(pi## / 180 * _
    I&),"0.00")
NEXT I&
```

Result

```
The Tangent of  5 degrees = 0.09
The Tangent of 10 degrees = 0.18
The Tangent of 15 degrees = 0.27
The Tangent of 20 degrees = 0.36
The Tangent of 25 degrees = 0.47
The Tangent of 30 degrees = 0.58
The Tangent of 35 degrees = 0.70
The Tangent of 40 degrees = 0.84
The Tangent of 45 degrees = 1.00
```

TCP ACCEPT statement

TCP ACCEPT statement

Purpose Accept an incoming request for communication from a specified TCP/IP port.

Syntax `TCP ACCEPT [#] fNum& AS newfNum&`

Remarks Accept an incoming connection request to the *fNum&* socket, and create a *newfNum&* socket handle to communicate with the new connection.

TCP ACCEPT is only valid with sockets opened using TCP OPEN SERVER.

See also TCP and UDP communications, TCP CLOSE, TCP LINE INPUT, TCP NOTIFY, TCP OPEN, TCP PRINT, TCP RECV, TCP SEND, UDP OPEN

TCP CLOSE statement

TCP CLOSE statement

Purpose Close a previously opened TCP/IP port.

Syntax `TCP CLOSE [#] fNum&`

Remarks Close the previously opened TCP/IP port specified by *fNum&*.

See also TCP and UDP communications, TCP ACCEPT, TCP LINE INPUT, TCP NOTIFY, TCP OPEN, TCP PRINT, TCP RECV, TCP SEND, UDP CLOSE

TCP LINE INPUT statement

TCP LINE INPUT statement

Purpose Receive a line of text from a specified TCP/IP port.

Syntax **`TCP LINE [INPUT] [#] fNum&, Buffer$`**

Remarks Receive a line of text from the *fNum&* TCP/IP port, and place the data in *Buffer$*. If no bytes are available, *Buffer$* will be empty (a null string). If TCP LINE did not receive a complete line of text (terminated by a $CRLF character pair), EOF(*fNum&*) will return TRUE (non-zero).

If a time-out occurs, ERR will be set to indicate a run-time Error 24 ("Device timeout"). See TCP OPEN to specify the TCP socket timeout value.

The EOF function may also be used with TCP LINE (and COMM LINE) to detect that an incomplete line was received. Normally, the TCP LINE statement reads data until a $CRLF character pair is found, and in that case, EOF will return false (zero). However, even if no $CRLF has been found, TCP LINE will return if no additional data is available. In that case, TCP LINE will return whatever data has been accumulated, and set EOF to logical TRUE (non-zero).

In many cases, it would be prudent to test EOF after every TCP LINE statement to verify that a full line has been received. In some cases, you may wish to execute the statement one or more additional times, combining the data, in order to obtain a full line of text.

See also TCP and UDP communications, EOF, TCP ACCEPT, TCP CLOSE, TCP NOTIFY, TCP OPEN, TCP PRINT, TCP RECV, TCP SEND, UDP RECV

TCP NOTIFY statement

TCP NOTIFY statement

Purpose Designate which TCP/IP events will generate a notification message.

Syntax **`TCP NOTIFY [#] fNum&, {SEND | RECV | ACCEPT | CONNECT | CLOSE} TO hWnd& AS wMsg&`**

Remarks Designates which events (SEND, RECV, ACCEPT, CONNECT and CLOSE) will generate a *wMsg&* notification message to the window procedure (callback) of the GUI window or dialog whose window handle is contained in *hWnd&*.

Your program defines the *wMsg&* value, and this value should be equal or larger than % WM_USER + 500 to avoid conflict with other (common) callback message values.

When the nominated callback function receives the *wMsg&* notification, the *wParam&* parameter identifies the operating system's handle of the socket (see FILEATTR), the low-order Word of *lParam&* specifies the code of the event (see table below), and the high-order Word of *lParam&* contains the error code (if any).

LO(WORD, *lParam&*)	Definition
`%FD_READ`	Data is available to be read from the socket.
`%FD_WRITE`	The socket is ready for data to be written.
`%FD_ACCEPT`	The socket is able to accept a new connection.
`%FD_CONNECT`	The connection has been established.
`%FD_CLOSE`	The socket has been closed.

Notification messages do not arrive in unabated or continuous streams. That is, once a particular notification message arrives, it will not be sent again until the initial message is acted upon. For example, if a %FD_READ notification is received, it will not be resent until after a TCP RECV statement is executed.

The Winsock error codes are listed in WINSOCK2.INC, prefixed with %WSAE.

See also TCP and UDP communications, TCP ACCEPT, TCP CLOSE, TCP LINE INPUT, TCP OPEN, TCP PRINT, TCP RECV, TCP SEND, UDP NOTIFY

TCP OPEN statement

TCP OPEN statement

Purpose	Enable an application to communicate with a TCP/IP server or client using the TCP protocol over Winsock.
Syntax	*As a client:* **TCP OPEN {PORT *p&* | *srvc$*} AT *address$* AS [#] *fNum&* [TIMEOUT *timeoutval&*]** As a server: **TCP OPEN SERVER [ADDR *ip&*] {PORT *p&* | *srvc$*} AS [#] *fNum&* [TIMEOUT *timeoutval&*]**
Remarks	Open a TCP/IP port or service for communication, either as a client or as a server.
SERVER	If the keyword server is included, the TCP port is opened as a TCP/IP server; otherwise, it is opened as a TCP/IP client.
ADDR *ip&*	As a server, if you specify the optional ADDR *ip&*, the TCP server monitors connections at the specified *ip&* address. Otherwise, the primary IP address for the computer is used by default.
PORT *p&*	As a client, PORT identifies the server port that the client attempts to connect to. As a server, PORT identifies the port the server will monitor for connection requests. You may specify either a port number or a service name, but not both.
srvc$	If the port number is not specified, a service name must be specified instead. A service name takes the form of "http", "smtp", or "ftp", etc. You may specify either a port number or a service name, but not both.
AT *address$*	As a client, *address$* identifies the address to connect with. *address$* can be a domain such as "powerbasic.com", or a dotted IP address in string form, such as "127.0.0.1".
fNum&	A file number such as #1, or a variable with a value obtained using the FREEFILE function.
TIMEOUT	The optional TIMEOUT value allows you to specify how long a TCP SEND, RECV, PRINT, or LINE operation should wait for completion, in milliseconds (*mSec*). If the specified number of milliseconds elapses without a response, the TCP operation will fail, and the ERR system variable will be set to indicate a run-time Error 24 ("Device timeout"). The default timeout is 60000 milliseconds (60 seconds).
See also	TCP and UDP communications, FREEFILE, TCP ACCEPT, TCP CLOSE, TCP LINE INPUT, TCP NOTIFY, TCP PRINT, TCP RECV, TCP SEND, UDP OPEN

Example

```
' Client TCP/IP example - retrieve a web page
#COMPILE EXE

FUNCTION PBMAIN() AS LONG
  LOCAL Buffer$, Site$, File$, Entire_page$
  LOCAL Length&

  Site$ = "www.powerbasic.com"
  File$ =
"http://www.powerbasic.com/support/forums/Forum2/HTML/000031.html"

  ' Connecting...
  TCP OPEN "http" AT Site$ AS #1 TIMEOUT 60000

  ' Could we connect to site?
  IF ERR THEN
      BEEP
      EXIT FUNCTION
  END IF
```

```
    ' Send the GET request...
    TCP PRINT #1, "GET " & File$ & " HTTP/1.0"
    TCP PRINT #1, "Referer: http://www.powerbasic.com/"
    TCP PRINT #1, "User-Agent: TCP OPEN Example (www.powerbasic.com)
    TCP PRINT #1, ""

    ' Retrieve the page...
    DO
      TCP RECV #1, 4096, Buffer$
      Entire_page = Entire_page + Buffer$
    LOOP WHILE ISTRUE LEN(Buffer$) AND ISFALSE ERR

    ' Close the TCP/IP port...
    TCP CLOSE #1
  END FUNCTION
```

TCP PRINT statement

TCP PRINT statement

Purpose Write a string to a nominated TCP/IP port.

Syntax `TCP PRINT [#] fNum&, string_expression[;]`

Remarks Write the data in *string_expression* to the *fNum&* TCP/IP port. If the optional semi-colon is not specified, a carriage-return and linefeed pair ($CRLF or CHR$(13,10)) is also sent.

The TCP PRINT statement does not return until *string_expression* has been sent, or an error occurs. That is, TCP PRINT is a synchronous or "blocking" statement. If a time-out occurs, ERR will be set to indicate a run-time Error 24 ("Device timeout"). See TCP OPEN to specify the TCP socket timeout value.

See also TCP and UDP communications, TCP ACCEPT, TCP CLOSE, TCP LINE INPUT, TCP NOTIFY, TCP OPEN, TCP RECV, TCP SEND, UDP OPEN

TCP RECV statement

TCP RECV statement

Purpose Receive data from a specified TCP/IP port.

Syntax `TCP RECV [#] fNum&, count&, Buffer$`

Remarks Receive *count&* bytes from the *fNum&* TCP/IP port and place them in *Buffer$*. If *count&* bytes are not available, *Buffer$* will receive whatever bytes are available and EOF(*fNum&*) will return TRUE (non-zero).

Typically used in a

to retrieve a stream of data, a TCP RECV loop should be terminated if *Buffer$* returns an empty , or if EOF(*fNum&*) returns TRUE, or if ERR becomes set. If a time-out occurs, ERR will be set to indicate a run-time Error 24 ("Device timeout"). See TCP OPEN to specify the TCP socket timeout value.

See also TCP and UDP communications, EOF, TCP ACCEPT, TCP CLOSE, TCP LINE INPUT, TCP NOTIFY, TCP OPEN, TCP PRINT, TCP SEND, UDP RECV

TCP SEND statement

TCP SEND statement

Purpose Write a string to a nominated TCP/IP port.

Syntax **TCP SEND [#] *fNum&, string_expression***

Remarks Write the specified *string_expression* to the TCP/IP port specified by *fNum&*.

The TCP SEND statement does not return until *string_expression* has been sent, or an error occurs. That is, TCP SEND is a synchronous or "blocking" statement. If a time-out occurs, ERR will be set to indicate a run-time Error 24 ("Device timeout"). See TCP OPEN to specify the TCP socket timeout value.

See also TCP and UDP communications, TCP ACCEPT, TCP CLOSE, TCP LINE INPUT, TCP NOTIFY, TCP OPEN, TCP PRINT, TCP RECV, UDP SEND

THREAD CLOSE statement

THREAD CLOSE statement

Purpose Release the handle of a running thread.

Syntax **THREAD CLOSE *hThread* TO *lResult&***

Remarks THREAD CLOSE releases the *thread handle* of the thread identified by the DWORD value *hThread* (see THREAD CREATE).

If successful, *lResult&* is TRUE (non-zero); otherwise, it is FALSE (zero). If a thread is not closed once it has completed, it will continue to take up memory and CPU resources. Note that THREAD CLOSE does not stop a thread if it is still running; it simply releases the thread's handle (i.e., the resources used to track the thread), and the thread itself will continue to run.

Once a thread handle is released, the value stored in *hThread* becomes undefined. On this basis, thread handles should not be released until there is no further need to test the thread status or change the suspend count for a thread. If a thread does not need to be monitored, its handle can be released immediately after the THREAD CREATE statement, and the threads resources will be freed automatically when the thread terminates naturally. Best practice suggests that after releasing a thread handle, the thread handle variable should be set to 0, to set it apart from other valid thread handle variables.

Once a thread has exited, it is not possible to restart the same thread (as identified by *hThread*). However, a fresh thread can be executed, using the same target thread Function, and resulting in a new thread handle which will identify the new thread.

Restrictions THREAD CLOSE will always execute successfully provided *hThread* contains a valid thread handle value. THREAD CLOSE generates no run-time errors; all exceptions are reported in the return value *lResult&*.

The *WaitForSingleObject* API function can be used wait until a nominated thread has finished executing. Similarly, the *WaitForMultipleObjects* API can be used to wait for one, two, or all secondary threads (to a maximum of 64 or %MAXIMUM_WAIT_OBJECTS) to complete before continuing on. Such functions can be very useful when a program creates a set of "worker" threads to process data, and the primary thread can then sit idle until all the worker threads have completed all their work. At that point, the primary thread may gather the results of the worker threads, etc.

It is also useful to understand that these kind of *wait* functions are very efficient and use almost no CPU time or resources while they are waiting; however, care must be exercised to avoid a deadlock or circular suspension. For example, a deadlock condition could occur if thread A is halted while it waits for thread B, which in turn has a suspend count that might only be adjustable by Thread A. Similarly, an infinite loop in one thread may also halt any other thread that is waiting for it to terminate.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

See also FUNCTION/END FUNCTION, THREAD Code Group, THREAD CREATE, THREAD Object, THREAD RESUME, THREAD STATUS, THREAD SUSPEND, THREADCOUNT, THREADED, THREADID

THREAD Code Group

Keyword Template

Purpose

Syntax

Remarks

See also

Example

THREAD Code Group

Purpose The

Code Group offers a collection of statements which allow you to create and manipulate additional threads of execution in your programs.

Syntax

```
THREAD DirectorWord [params]
THREAD DirectorWord [params] TO ReturnVariable(s)
```

Remarks A Windows thread is a smaller "program-within-a-program", that runs concurrently with the main thread and other threads in the same application program. Threads provide powerful ways for an application to perform several tasks at the same time.

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. For that reason, PowerBASIC has introduced the concept of a THREAD OBJECT. While the THREAD Code Group will be supported for some time, we recommend that all new code use THREAD OBJECTS exclusively. They provide much greater control, and much better thread parameter handling for the programmer.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed referencing the same thread.

See also FUNCTION/END FUNCTION, THREAD CLOSE, THREAD CREATE, THREAD GET PRIORITY, THREAD Object, THREAD RESUME, THREAD STATUS, THREAD SUSPEND, THREADCOUNT, THREADED, THREADID, THREADSAFE option descriptor

THREAD CREATE statement

THREAD CREATE statement

Purpose Create a Windows thread, which is a smaller "program-within-a-program", that runs concurrently with the main thread and other threads in the same application program. Threads provide powerful ways for an application to perform several tasks at the same time.

Syntax

```
THREAD CREATE FuncName(param) [StackSize,] [SUSPEND] TO hThread
```

Remarks THREAD CREATE creates and begins execution of a new thread Function identified by *FuncName*. *FuncName* is specified without quotation marks. This function must take exactly one Long-integer or Double-word (DWORD) parameter by value (BYVAL). For example:

```
THREAD FUNCTION MyThreadFunction(BYVAL x AS LONG) AS LONG
  ' Thread code goes here
END FUNCTION
' more code here
THREAD CREATE MyThreadFunction(var&) TO hThread???
```

The 32-bit parameter passed to the thread may be used to pass a value such as a programmer-defined ID or window handle to *post* "progress" messages back to a GUI window/dialog running in another thread. A more common use for the parameter is to pass the address to a UDT or other data structure. Passing an address this way can enable the thread to use a pointer to access large volumes of data that reside outside of the thread. For example:

```
THREAD FUNCTION MyThread(BYVAL y AS DWORD) AS DWORD
  DIM x AS MyUDT POINTER
  x = y  ' Set the pointer from the DWORD param
  ' From here we can access all of the UDT member elements
  ' using the standard @x pointer syntax
END FUNCTION
' more code here
DIM x AS MyUDT, hThread???
' Initialize the members of x here
THREAD CREATE MyThread( VARPTR(x) ) TO hThread???
' more code here
```

Note that data passed this way is subject to the notes (below) concerning GLOBAL and STATIC variables, in order to avoid synchronization problems during context-switching.

The return value of the thread Function is retrieved with the THREAD STATUS statement (once the thread has completed execution).

StackSize A long integer expression to specify the requested size of the stack for this newly created thread. This value should always be specified in increments of 64K (65536). If this parameter is omitted, the size of the stack for the main thread will be used.

SUSPEND Execution of the thread begins immediately unless the SUSPEND option is included. In that case, the *suspend count* for the thread will be initially set to 1, and the thread will be initially suspended. The THREAD RESUME statement is used to decrease the suspend count of a thread by 1, and when the suspend count reaches 0, the thread will start (resume) execution. Controlling the suspend state of a thread requires the thread handle value be retained until such time as the thread can be closed or left to run unmonitored.

hThread If successful, THREAD CREATE returns a Double-word (or Long-integer) handle in *hThread*, or zero (0) if the thread was not started. This handle is used with the other

to control the suspend count, and to release the thread handle, etc. Also see THREAD CLOSE for more information on monitoring, closing, and waiting for threads to complete.

FuncName The name of the thread function to execute as a thread. A thread Function must comply exactly with the following syntax:

```
THREAD FUNCTION ThreadFuncName (BYVAL param AS {LONG | DWORD}) AS {LONG
| DWORD}
```

Restrictions The THREAD CREATE statement generates no run-time errors; all exceptions are reported as a zero stored in the return value *hThread*. However, the target thread Function must be located in the same compiled module as the THREAD CREATE statement. That is, a thread Function may not be an imported Function.

Additionally, a thread Function may not be directly called or executed, *except* by a THREAD CREATE statement. This restriction is imposed to ensure that PowerBASIC run-time library can maintain a thread-safe state at all times, correctly allocate and deallocate internal thread-local storage, and the various

(such as THREADCOUNT) can return accurate values.

One situation that can arise is where a Function may need to be invoked both directly and used as a thread Function. The easiest solution is to create a small *wrapper* Function for the Function, then use THREAD CREATE with the wrapper Function when a thread is required, or continue to call the original Function directly when a separate thread is not required. For example:

```
FUNCTION WorkerFunc(BYVAL x AS LONG) AS LONG
  ' code here
END FUNCTION

THREAD FUNCTION WorkerThread(BYVAL x AS LONG) AS LONG
  FUNCTION = WorkerFunc(x)
END FUNCTION

' more code here

' Execute the worker function directly, thus:
lResult& = WorkerFunc(var&)

' Execute the worker thread as a thread, using
' the wrapper function:
THREAD CREATE WorkerThread(var&) TO hThread???
```

A thread can determine its own ID with the THREADID function. Note: a thread ID is not interchangeable with a thread handle.

Threads are initialized and started asynchronously, so it is wise to give the operating system a small amount of time to perform thread initialization before using the THREADCOUNT function to monitor the thread.

Once a thread has exited, it is not possible to restart the same thread as identified by *hThread* - however, a new thread can be initiated using the same Function (which naturally provides a new *hThread* handle value). In addition, the same thread Function can be launched multiple times to create a set of identical threads executing the same code.

As each thread is created, it is assigned its own "private" stack frame. Therefore, LOCAL and REGISTER variables are private to each thread, and are automatically "*thread-safe*".

Exercise care when using GLOBAL and STATIC variables that may be accessed by more than one thread at the same time. If one thread is part way through storing data at the point where another thread begins to read the same memory block, it can result in the second thread reading only partially updated (i.e., invalid) data. The point where one thread is suspended so that another can run is called a "*context-switch*". In these situations, the use of Windows' synchronization functions (such as *Critical Sections* and *Mutexes*) may be employed to create thread-safe code.

Thread-safe code is deemed to be unaffected by context-switching, regardless of when context-switching occurs. Local variables, being stored in a "private" stack frame, are not affected by context-switching.

Local variable storage created by each thread is automatically freed when the thread Function terminates, in the same manner as a normal Sub, Function, Method, or Property. However, the thread handle must be explicitly freed with a THREAD CLOSE statement. The THREAD CLOSE can occur at any time, since it only frees the thread handle and has no other impact on the running thread. If the thread result value is not required (or the thread state does not need to be altered), THREAD CLOSE can be used immediately after the THREAD CREATE statement, leaving the thread to run its course.

For more information on threading and synchronization techniques, please refer to MSDN http://msdn.microsoft.com.

The PowerBASIC run-time library is thread-safe and reentrant.

See also FUNCTION/END FUNCTION, THREAD CLOSE, THREAD Code Group, THREAD GET PRIORITY, THREAD Object, THREAD RESUME, THREAD STATUS, THREAD SUSPEND, THREADCOUNT, THREADED, THREADID

Example

```
SUB SpawnThreads()
  LOCAL x AS LONG
  LOCAL s AS LONG
  DIM hThread(10) AS LOCAL DWORD

  FOR x = 1 TO 10
    THREAD CREATE MyThread(x) TO hThread(x)
    SLEEP 50
  NEXT

  DisplayText "10 Threads Started! " + _
    "Wait for them to finish!"

  DO
    FOR x = 1 TO 10
      SLEEP 0
      THREAD STATUS hThread(x) TO s
      IF s <> &H103 AND s <> 0 THEN ITERATE DO
    NEXT
  LOOP WHILE s

  FOR x = 1 TO 10
    THREAD CLOSE hThread(x) TO s
  NEXT x

  DisplayText "Finished!"
END SUB

' The following is executed as a thread Function!
THREAD FUNCTION MyThread (BYVAL x AS LONG) AS LONG
  LOCAL n AS LONG
  LOCAL t AS SINGLE

  DisplayText "Begin Thread" + STR$(x)
  t = TIMER

  FOR n = 1 TO 10
    SLEEP 100 + 100 * x
  NEXT n

  t = TIMER - t
  DisplayText "End Thread" + STR$(x) + _
    " Elapsed time = " + STR$(t,5)

END FUNCTION
```

THREAD GET PRIORITY statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

THREAD GET PRIORITY statement

Purpose Retrieve the Priority Value for a

.

Syntax **THREAD GET PRIORITY *hThread* TO *lResult&***

Remarks THREAD GET PRIORITY retrieves the priority value for the thread specified by the thread handle (*hThread*). The thread handle is returned by the THREAD CREATE statement at the time the thread is created. If *hThread* is zero (0), the thread which is currently executing is presumed. The retrieved priority value is assigned to the long or dword variable designated by *lResult&*. A thread ID cannot be used in place of a thread handle.

The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL  =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL  =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

THREAD Object

Keyword Template

Purpose

Syntax

Remarks

See also

Example

THREAD Object New!

Purpose A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal* AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a
option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER

 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
```

```
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE         = -15
%THREAD_PRIORITY_LOWEST       =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL       =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST      =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE         = -15
%THREAD_PRIORITY_LOWEST       =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL       =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST      =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions

Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

See also

PowerTime, THREAD Code Group

Example

```
CLASS MyClass
  INSTANCE ThreadParam as DataFace

  THREAD METHOD MAIN() AS LONG
    x& = ThreadParam.GetANumber()
    MsgBox DEC$(x&)
  END METHOD

  INTERFACE MyFace
    INHERIT IPOWERTHREAD

    METHOD abc
      END METHOD
    END INTERFACE
END CLASS

CLASS DataClass
  INTERFACE DataFace
    INHERIT DUAL

    METHOD GetANumber() AS LONG
    METHOD = 77
  END METHOD

  END INTERFACE
END CLASS

FUNCTION PBMain()
  LOCAL xx AS MyFace
  LET xx = CLASS "MyClass"

  LOCAL oo AS DataFace
  LET oo = CLASS "DataClass"

  xx.launch(oo)
  xx.join(xx, 0)
END FUNCTION
```

THREAD RESUME statement

THREAD RESUME statement

Purpose Resume execution of a Windows thread.

Syntax `THREAD RESUME hThread TO lResult&`

Remarks THREAD RESUME decreases the *suspend count* of the thread identified by the 32-bit DWORD value stored in *hThread* (see THREAD CREATE). If it succeeds, the *lResult&* value is the thread's previous suspend count; otherwise, it is -1.

Execution of a suspended thread resumes when the suspend count of a thread is decremented to zero. If the SUSPEND option is included in the associated THREAD CREATE statement, the thread will have an initial suspend count of 1. In that case, execution of the thread will only begin when a THREAD RESUME statement is executed, using the thread handle stored in *hThread* to identify the thread.

Restrictions The THREAD RESUME statement generates no run-time errors; all exceptions are reported in the return value *lResult&*. A thread ID cannot be used interchangeably with a thread handle. A thread can suspend itself by incrementing its own suspend count, but logically, cannot decrement its own suspend count.

See also FUNCTION/END FUNCTION, THREAD CLOSE, THREAD Code Group, THREAD CREATE, THREAD Object, THREAD STATUS, THREAD SUSPEND, THREADCOUNT, THREADED, THREADID

THREAD SET PRIORITY statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

THREAD SET PRIORITY statement

Purpose Sets the Priority Value for a

.

Syntax `THREAD SET PRIORITY hThread, Priority&`

Remarks THREAD SET PRIORITY assigns a new priority value to the thread specified by the thread handle (*hThread*). The thread handle is returned by the THREAD CREATE statement at the time the thread is created. If *hThread* is zero (0), the thread which is currently executing is presumed. A thread ID cannot be used in place of a thread handle.

The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

See also PROCESS GET PRIORITY, PROCESS SET PRIORITY, THREAD Code Group, THREAD CREATE, THREAD GET PRIORITY, THREAD Object

THREAD STATUS statement

THREAD STATUS statement

Purpose Retrieve the Status of a Windows thread.

Syntax `THREAD STATUS hThread TO lResult&`

Remarks THREAD STATUS assigns the status of the thread identified by the DWORD value in *hThread* (see THREAD CREATE) to *lResult&*.

If the function fails, *lResult&* is set to zero. If the thread is still running, the system value &H103 is assigned. If the thread has terminated and the thread handle has not yet been closed, the return value from the thread Function is assigned to *lResult&*. To wait for one or more threads to complete execution, use the WaitForSingleObject or WaitForMultipleObjects API functions - see THREAD CLOSE for more information.

The number of currently running threads in a module can be determined with the THREADCOUNT function.

Restrictions The THREAD STATUS statement generates no run-time errors; all exceptions are reported in the return value *lResult&*. A thread ID cannot be used in place of a thread handle.

See also FUNCTION/END FUNCTION, THREAD CLOSE, THREAD Code Group, THREAD CREATE, THREAD Object, THREAD RESUME, THREAD SUSPEND, THREADCOUNT, THREADED, THREADID

THREAD SUSPEND statement

THREAD SUSPEND statement

Purpose Suspend execution of a Windows thread.

Syntax `THREAD SUSPEND hThread TO lResult&`

Remarks THREAD SUSPEND adds 1 to the *suspend count* of the thread specified by *hThread* (see THREAD CREATE). If it succeeds, the *lResult&* value is the thread's previous suspend count; otherwise, it is -1. A thread is always suspended if it has a suspend count of 1 or higher.

To decrement the suspend count of a thread, use the THREAD RESUME statement. A suspended thread will only resume execution when its suspend count is decremented to 0.

Restrictions The THREAD SUSPEND statement generates no run-time errors; all exceptions are reported in the return value *lResult&*. A thread ID cannot be used interchangeably with a thread handle. A thread can suspend itself by incrementing its own suspend count.

See also FUNCTION/END FUNCTION, THREAD CLOSE, THREAD Code Group, THREAD CREATE, THREAD Object, THREAD RESUME, THREAD STATUS, THREADCOUNT, THREADED, THREADID

THREADCOUNT function

THREADCOUNT function

Purpose Return the number of PowerBASIC-created active threads that exist in a module.

Syntax `lCount& = THREADCOUNT`

Remarks Applications will return a THREADCOUNT of at least 1, which is attributed to the "primary" application thread. Additional threads created by the application or module with the THREAD CREATE function will also be included in the tally returned by THREADCOUNT.

THREADCOUNT can be useful for when a "controlling thread" needs to poll the state of a collection of "worker threads" as they complete a set of tasks. However, care should be exercised if other (unrelated) threads may also be running in the same module - in such cases, using THREAD STATUS is the preferred solution. If polling is not desired, the WaitForMultipleObjects API function can also be useful - see THREAD CLOSE for more information.

Restrictions THREADCOUNT includes threads that have had their thread handle released with THREAD CLOSE, yet are still running.

Threads are initialized and started asynchronously, so it is wise to give the operating system a small amount of time to perform thread initialization before using the THREADCOUNT function to monitor the thread.

A thread Function may not be directly called or executed, except by a THREAD CREATE statement. This restriction is imposed to ensure that PowerBASIC run-time library can maintain a thread-safe state at all times, correctly allocate and deallocate internal thread-local storage), and functions such as THREADCOUNT can return accurate values. See THREAD CREATE for more information and solutions.

See also FUNCTION/END FUNCTION, THREAD CLOSE, THREAD Code Group, THREAD CREATE, THREAD Object, THREAD RESUME, THREAD STATUS, THREAD SUSPEND, THREADED, THREADID

Example

```
THREAD FUNCTION tZ(BYVAL x&) AS LONG
  ' Wait for a random time
  SLEEP x& * RND(1,1000)
  FUNCTION = 1
END FUNCTION

FUNCTION PBMAIN
  ' Create 10 threads
  FOR x& = 1 TO 10
    THREAD CREATE tZ(x&) TO hThread???
    THREAD CLOSE hThread??? TO lResult&
  NEXT x&

  'Wait until the threads are all done
  DO
    SLEEP 100
  LOOP WHILE THREADCOUNT > 1
END FUNCTION
```

THREADED statement

THREADED statement

Purpose Declare thread-local variables.

Syntax

```
THREADED variable[()] [AS type] [, variable[()]]
THREADED variable[()] [, variable[()]] [, ...] AS type
```

Remarks Threaded variables are global to every Sub, Function, Method, and Property but are not shared across threads. Each thread has its own independent set of thread-local variables.

To declare an array as a threaded variable, use an empty set of parentheses in the variable list: You can then use the DIM statement to dimension the array.

```
THREADED MyArray%()
THREADED StringArray() AS STRING
```

The THREADED statement may, optionally, accept a list of variables, all of which are defined by the type descriptor keyword that follows them. For example:

```
THREADED aaa, bbb, ccc AS INTEGER
THREADED vptr, aptr() AS LONG PTR
```

Restrictions DEF*type* has no effect on variables defined by a THREADED statement.

See also DIM, GLOBAL, INSTANCE, LOCAL, STATIC

Example

```
THREADED xxx, yyy, zzz AS INTEGER
THREADED vptr, aptr() AS LONG PTR
```

THREADID function

THREADID function

Purpose Return a Long-integer thread identifier of the current thread.

Syntax ***thrdID&*** **= THREADID**

Remarks The thread ID value is returned for the thread that is currently executing. The Thread ID is intended for use with the various (advanced) thread-related API functions provided by Windows.

Restrictions The thread ID value cannot be used interchangeably with the thread handle returned by THREAD CREATE.

See also FUNCTION/END FUNCTION, THREAD CLOSE, THREAD CREATE, THREAD RESUME, THREAD STATUS, THREAD SUSPEND, THREADED

TIME$ system variable

TIME$ system variable

Purpose Read and/or set the system time.

Syntax To read the time:

***s$*** **= TIME$**

To set the time:

TIME$ = ***string_expression***

Remarks The system variable TIME$ contains an eight-character

that represents the time of the system clock in the form "*hh:mm:ss*", where *hh* is hours (in 24-hour military form), *mm* is minutes, and *ss* is seconds.

Assigning *string_expression* to TIME$ resets the system clock. *string_expression* must contain time information in military (24-hour) format. Minutes and seconds information can be omitted. For example:

```
TIME$ = "12"       'set clock to 12 noon
TIME$ = "13:01"    'set clock to 1:01 PM
TIME$ = "13:01:30" 'set clock to 30 sec after 1:01 PM
TIME$ = "0:01"     'set clock to 1 min after midnight
```

Use the TIMER function to return the number of seconds that have elapsed since midnight.

See also DATE$, MONTHNAME$, POWERTIME, TIMER, TIX

TIMER function

TIMER function

Purpose Return the number of seconds that have elapsed since midnight.

Syntax `y = TIMER`

Remarks TIMER returns the number of seconds since midnight as a Double-precision floating-point value. The resolution is about 1/100 of a second on NT-based platforms, or 1/18th of a second on earlier platforms.

See also DATE$, TIME$, TIX

Example

```
OldTime$ = TIME$ ' Current time
TIME$ = "12"     ' Noon
NoonSec$ = FORMAT$(TIMER, "#,")
x$ = "Noon is " + NoonSec$ + " seconds past midnight"
TIME$ = OldTime$ ' Restore time
```

Result `Noon is 43,200 seconds past midnight`

TIX statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

TIX statement

Purpose Measures elapsed CPU cycles.

Syntax

```
TIX QuadVar
TIX END QuadVar
```

Remarks The TIX statement offers you the ability to measure elapsed CPU cycles, the smallest timing increment possible. Modern processors typically execute billions of cycles per second. This can be beneficial for comparing the execution speed of various styles of coding in PowerBASIC.

TIX *QuadVar*

The first form of the TIX statement retrieves the current value of the cycle counter and assigns it to the Quad Integer variable.

TIX END *QuadVar*

The second form of the TIX statement retrieves the current value of the cycle counter. The value in the QuadVar is subtracted from it, and the result is assigned to QuadVar.

To measure the total cycle count for a particular set of statements, you would write:

```
TIX CycleCount&&
  ' statements to measure go here
TIX END CycleCount&&
```

At this point, CycleCount&& contains the elapsed number of CPU cycles.

See also #ALIGN, TIMER

TOOLBAR ADD BUTTON statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

TOOLBAR statement IMPROVED

Purpose A ToolBar control contains one or more buttons which act as shortcuts to menu items. The TOOLBAR statement is used to manipulate a TOOLBAR control.

Syntax

```
TOOLBAR ADD BUTTON hDlg, ID, image&, cmd&, style&, text$ [AT item&] [CALL
callback]
TOOLBAR ADD SEPARATOR hDlg, ID, size& [,cmd&] [AT item&]
TOOLBAR DELETE BUTTON hDlg, id&, [BYCMD] item&
TOOLBAR GET STATE hDlg, ID, [BYCMD] item& TO datav&
TOOLBAR GET COUNT hDlg, ID TO datav&
TOOLBAR SET IMAGELIST hDlg, ID, hLst, ListType&
TOOLBAR SET STATE hDlg, ID, [BYCMD] item&, state&
```

hDlg Handle of the dialog that owns the ToolBar.

hLst Handle of the ImageList to be used for graphical items.

id& The control identifier assigned with CONTROL ADD TOOLBAR.

cmd& Command id number associated with this button.

image& Image number selected (1=first, 2=second, etc.)

item& A data item number. First=1, second=2...

size& Size of the item expressed in pixels.

state& A state descriptor to define specific attributes.

style& Style descriptor bits for this button.

text$ A text

to be displayed on this button.

type& A type descriptor to define specific attributes.

callback A callback function which receives messages for the control.

datav& A long integer variable to which result data is assigned.

txtv$ A string variable to which result text is assigned.

Remarks A TOOLBAR control contains one or more buttons, each of which normally corresponds to a menu item. It is generally placed at the top of the client area of a dialog. When the user "presses" a tool bar button, the program reacts in the same way as if the command had been selected from a menu. It simply acts as a shortcut to common menu commands.

In each of the following descriptions, the TOOLBAR is referenced by the dialog handle (*hDlg*) and id&. In some cases a specific button is chosen with the *item&* parameter. If the BYCMD option is included, *item&* specifies the command id number of the button to be used. If not, *item&* describes the button by its position on the TOOLBAR. Since separators are considered to be a special class of button by the operating system, they must be counted when you calculate a position item number. Positions are always indexed to one (1=first, 2=second, and so on).

TOOLBAR ADD BUTTON *hDlg*, *ID*, *image&*, *cmd&*, *style&*, *text$* [AT *item&*] [CALL *callback*]

A button is added to this TOOLBAR. The image to be displayed is selected from the attached IMAGELIST based upon the parameter *image&* (1=first, 2=second, etc.). The *cmd&* parameter specifies the command id number to be executed (with %WM_COMMAND) when the button is pressed. The *style&* parameter describes the style of the button from the following most often used attributes:

%BTNS_AUTOSIZE	The width of the button is calculated by the system, based upon the text and the image.
%BTNS_BUTTON	The button behaves like a standard push button.
%BTNS_CHECK	The button is dual-state which toggles between the pressed and nonpressed state each time it's clicked.
%BTNS_GROUP	Defines a group of buttons. When combined with the check style, it creates a button that stays pressed until another button in the group is pressed. This is similar to an option button or radio button.
%BTNS_CHECKGROUP	A combination of check and group styles.
%BTNS_DROPDOWN	Creates a drop-down style button that can display a list when clicked. Drop-down buttons send a %TBN_DROPDOWN notification instead of %WM_COMMAND.
%BTNS_NOPREFIX	The button text will not have an accelerator prefix associated with it.

The *text$* parameter specifies the text to be displayed on the button.

If the optional "AT *item&*" clause is included, the button is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

If the optional "CALL *callback*" clause is included, it specifies the name of a Callback Function that receives %WM_COMMAND messages when the button is clicked. If not specified, these command messages are sent to the dialog callback specified in

. Message routing by button allows you to easily determine which button generated the event.

If the Callback Function processes a message, it should return TRUE (non-zero) to prevent the message being passed unnecessarily to the dialog callback (if one exists). The dialog callback should also return TRUE if the notification message is processed by that Callback Function. Otherwise, the DDT engine processes unhandled messages.

TOOLBAR ADD SEPARATOR *hDlg*, *ID*, *size&* [,*cmd&*] [AT *item&*]

A separator is added to this TOOLBAR. It separates two buttons by the number of pixels specified in *size&*. It may be used to separate and distinguish two adjacent button groups (%tbstyle_group), or to just enhance the visual appearance. If the optional *cmd&* parameter is included, it's a unique numeric identifier for this separator. Of course, a separator can't be pressed like a button, so it doesn't literally allow a command to be sent. However, it may be used later with a BYCMD option in TOOLBAR DELETE, TOOLBAR SET STATE, etc. If the "AT *item&*" clause is included, the separator is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

TOOLBAR DELETE BUTTON *hDlg*, *ID*, [BYCMD] *item&*

A BUTTON or SEPARATOR, specified by *item&*, is deleted from the TOOLBAR. The parameter *item&* may be positional, or it may represent a command id number with BYCMD.

TOOLBAR GET COUNT *hDlg*, *ID* to *datav&*

The number of buttons (and separators) on the TOOLBAR is retrieved and assigned to the long integer variable specified by *datav&*.

TOOLBAR GET STATE *hDlg*, *ID*, [BYCMD] *item&* TO *datav&*

The state descriptor bits for a specific button are retrieved and assigned to the variable designated by *datav&*. The parameter *item&* tells which button to check -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits may consist of one or more of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.
%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

TOOLBAR SET IMAGELIST *hDlg*, *ID*, *hLst*, *type&*

The IMAGELIST specified by *hLst* is attached to this TOOLBAR control. The value of *ListType&* specifies the type of IMAGELIST:

0	Default images
1	Disabled images
2	Hot images

The graphical images contained in the IMAGELIST are displayed on the TOOLBAR buttons. Up to three IMAGELIST structures may be attached to each TOOLBAR control. The image to be displayed is determined by the specification made in TOOLBAR ADD BUTTON, and the current state of the button. When the TOOLBAR control is destroyed, any attached IMAGELIST is automatically destroyed.

TOOLBAR SET STATE *hDlg*, *ID*, [BYCMD] *item&*, *state&*

The state descriptor bits for the specified button are applied from the expression *state&*. The parameter *item&* tells which button to set -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits *state&* may consist of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.
%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

Example

TOOLBAR statement IMPROVED

Purpose	A ToolBar control contains one or more buttons which act as shortcuts to menu items. The TOOLBAR statement is used to manipulate a TOOLBAR control.
Syntax	**TOOLBAR ADD BUTTON *hDlg, ID, image&, cmd&, style&, text$* [AT *item&*] [CALL *callback*]** **TOOLBAR ADD SEPARATOR *hDlg, ID, size&* [,*cmd&*] [AT *item&*]** **TOOLBAR DELETE BUTTON *hDlg, id&,* [BYCMD] *item&*** **TOOLBAR GET STATE *hDlg, ID,* [BYCMD] *item&* TO *datav&*** **TOOLBAR GET COUNT *hDlg, ID* TO *datav&*** **TOOLBAR SET IMAGELIST *hDlg, ID, hLst, ListType&*** **TOOLBAR SET STATE *hDlg, ID,* [BYCMD] *item&, state&***
hDlg	Handle of the dialog that owns the ToolBar.
hLst	Handle of the ImageList to be used for graphical items.
id&	The control identifier assigned with CONTROL ADD TOOLBAR.
cmd&	Command id number associated with this button.
image&	Image number selected (1=first, 2=second, etc.)
item&	A data item number. First=1, second=2...
size&	Size of the item expressed in pixels.
state&	A state descriptor to define specific attributes.
style&	Style descriptor bits for this button.
text$	A text to be displayed on this button.
type&	A type descriptor to define specific attributes.
callback	A callback function which receives messages for the control.
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result text is assigned.

Remarks

A TOOLBAR control contains one or more buttons, each of which normally corresponds to a menu item. It is generally placed at the top of the client area of a dialog. When the user "presses" a tool bar button, the program reacts in the same way as if the command had been selected from a menu. It simply acts as a shortcut to common menu commands.

In each of the following descriptions, the TOOLBAR is referenced by the dialog handle (*hDlg*) and id&. In some cases a specific button is chosen with the *item&* parameter. If the BYCMD option is included, *item&* specifies the command id number of the button to be used. If not, *item&* describes the button by its position on the TOOLBAR. Since separators are considered to be a special class of button by the operating system, they must be counted when you calculate a position item number. Positions are always indexed to one (1=first, 2=second, and so on).

TOOLBAR ADD BUTTON *hDlg*, *ID*, *image&*, *cmd&*, *style&*, *text$* [AT *item&*] [CALL *callback*]

A button is added to this TOOLBAR. The image to be displayed is selected from the attached IMAGELIST based upon the parameter *image&* (1=first, 2=second, etc.). The *cmd&* parameter specifies the command id number to be executed (with %WM_COMMAND) when the button is pressed. The *style&* parameter describes the style of the button from the following most often used attributes:

%BTNS_AUTOSIZE	The width of the button is calculated by the system, based upon the text and the image.
%BTNS_BUTTON	The button behaves like a standard push button.
%BTNS_CHECK	The button is dual-state which toggles between the pressed and nonpressed state each time it's clicked.
%BTNS_GROUP	Defines a group of buttons. When combined with the check style, it creates a button that stays pressed until another button in the group is pressed. This is similar to an option button or radio button.
%BTNS_CHECKGROUP	A combination of check and group styles.
%BTNS_DROPDOWN	Creates a drop-down style button that can display a list when clicked. Drop-down buttons send a %TBN_DROPDOWN notification instead of %WM_COMMAND.
%BTNS_NOPREFIX	The button text will not have an accelerator prefix associated with it.

The *text$* parameter specifies the text to be displayed on the button.

If the optional "AT *item&*" clause is included, the button is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

If the optional "CALL *callback*" clause is included, it specifies the name of a Callback Function that receives %WM_COMMAND messages when the button is clicked. If not specified, these command messages are sent to the dialog callback specified in

. Message routing by button allows you to easily determine which button generated the event.

If the Callback Function processes a message, it should return TRUE (non-zero) to prevent the message being passed unnecessarily to the dialog callback (if one exists). The dialog callback should also return TRUE if the notification message is processed by that Callback Function. Otherwise, the DDT engine processes unhandled messages.

TOOLBAR ADD SEPARATOR *hDlg*, *ID*, *size&* [,*cmd&*] [AT *item&*]

A separator is added to this TOOLBAR. It separates two buttons by the number of pixels specified in *size&*. It may be used to separate and distinguish two adjacent button groups (%tbstyle_group), or to just enhance the visual appearance. If the optional *cmd&* parameter is included, it's a unique numeric identifier for this separator. Of course, a separator can't be pressed like a button, so it doesn't literally allow a command to be sent. However, it may be used later with a BYCMD option in TOOLBAR DELETE, TOOLBAR SET STATE, etc. If the "AT *item&*" clause is included, the separator is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

TOOLBAR DELETE BUTTON *hDlg*, *ID*, [BYCMD] *item&*

A BUTTON or SEPARATOR, specified by *item&*, is deleted from the TOOLBAR. The parameter *item&* may be positional, or it may represent a command id number with BYCMD.

TOOLBAR GET COUNT *hDlg*, *ID* to *datav&*

The number of buttons (and separators) on the TOOLBAR is retrieved and assigned to the long integer variable specified by *datav&*.

TOOLBAR GET STATE *hDlg*, *ID*, [BYCMD] *item&* TO *datav&*

The state descriptor bits for a specific button are retrieved and assigned to the variable designated by *datav&*. The parameter *item&* tells which button to check -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits may consist of one or more of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.
%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

TOOLBAR SET IMAGELIST *hDlg*, *ID*, *hLst*, *type&*

The IMAGELIST specified by *hLst* is attached to this TOOLBAR control. The value of *ListType&* specifies the type of IMAGELIST:

0	Default images
1	Disabled images
2	Hot images

The graphical images contained in the IMAGELIST are displayed on the TOOLBAR buttons. Up to three IMAGELIST structures may be attached to each TOOLBAR control. The image to be displayed is determined by the specification made in TOOLBAR ADD BUTTON, and the current state of the button. When the TOOLBAR control is destroyed, any attached IMAGELIST is automatically destroyed.

TOOLBAR SET STATE *hDlg*, *ID*, [BYCMD] *item&*, *state&*

The state descriptor bits for the specified button are applied from the expression *state&*. The parameter *item&* tells which button to set -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits *state&* may consist of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.
%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

Example

TOOLBAR statement IMPROVED

Purpose A ToolBar control contains one or more buttons which act as shortcuts to menu items. The TOOLBAR statement is used to manipulate a TOOLBAR control.

Syntax

```
TOOLBAR ADD BUTTON hDlg, ID, image&, cmd&, style&, text$ [AT item&] [CALL callback]
TOOLBAR ADD SEPARATOR hDlg, ID, size& [,cmd&] [AT item&]
TOOLBAR DELETE BUTTON hDlg, id&, [BYCMD] item&
TOOLBAR GET STATE hDlg, ID, [BYCMD] item& TO datav&
TOOLBAR GET COUNT hDlg, ID TO datav&
TOOLBAR SET IMAGELIST hDlg, ID, hLst, ListType&
TOOLBAR SET STATE hDlg, ID, [BYCMD] item&, state&
```

hDlg Handle of the dialog that owns the ToolBar.

hLst Handle of the ImageList to be used for graphical items.

id& The control identifier assigned with CONTROL ADD TOOLBAR.

cmd& Command id number associated with this button.

image& Image number selected (1=first, 2=second, etc.)

item& A data item number. First=1, second=2...

size& Size of the item expressed in pixels.

state& A state descriptor to define specific attributes.

style& Style descriptor bits for this button.

text$ A text
to be displayed on this button.

type& A type descriptor to define specific attributes.

callback A callback function which receives messages for the control.

datav& A long integer variable to which result data is assigned.

txtv$ A string variable to which result text is assigned.

Remarks A TOOLBAR control contains one or more buttons, each of which normally corresponds to a menu item. It is generally placed at the top of the client area of a dialog. When the user "presses" a tool bar button, the program reacts in the same way as if the command had been selected from a menu. It simply acts as a shortcut to common menu commands.

In each of the following descriptions, the TOOLBAR is referenced by the dialog handle (*hDlg*) and id&. In some cases a specific button is chosen with the *item&* parameter. If the BYCMD option is included, *item&* specifies the command id number of the button to be used. If not, *item&* describes the button by its position on the TOOLBAR. Since separators are considered to be a special class of button by the operating system, they must be counted when you calculate a position item number. Positions are always indexed to one (1=first, 2=second, and so on).

TOOLBAR ADD BUTTON *hDlg*, *ID*, *image&*, *cmd&*, *style&*, *text$* [AT *item&*] [CALL *callback*]

A button is added to this TOOLBAR. The image to be displayed is selected from the attached IMAGELIST based upon the parameter *image&* (1=first, 2=second, etc.). The *cmd&* parameter specifies the command id number to be executed (with %

WM_COMMAND) when the button is pressed. The *style&* parameter describes the style of the button from the following most often used attributes:

%BTNS_AUTOSIZE	The width of the button is calculated by the system, based upon the text and the image.
%BTNS_BUTTON	The button behaves like a standard push button.
%BTNS_CHECK	The button is dual-state which toggles between the pressed and nonpressed state each time it's clicked.
%BTNS_GROUP	Defines a group of buttons. When combined with the check style, it creates a button that stays pressed until another button in the group is pressed. This is similar to an option button or radio button.
%BTNS_CHECKGROUP	A combination of check and group styles.
%BTNS_DROPDOWN	Creates a drop-down style button that can display a list when clicked. Drop-down buttons send a %TBN_DROPDOWN notification instead of %WM_COMMAND.
%BTNS_NOPREFIX	The button text will not have an accelerator prefix associated with it.

The *text$* parameter specifies the text to be displayed on the button.

If the optional "AT *item&*" clause is included, the button is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

If the optional "CALL *callback*" clause is included, it specifies the name of a Callback Function that receives %WM_COMMAND messages when the button is clicked. If not specified, these command messages are sent to the dialog callback specified in

. Message routing by button allows you to easily determine which button generated the event.

If the Callback Function processes a message, it should return TRUE (non-zero) to prevent the message being passed unnecessarily to the dialog callback (if one exists). The dialog callback should also return TRUE if the notification message is processed by that Callback Function. Otherwise, the DDT engine processes unhandled messages.

TOOLBAR ADD SEPARATOR *hDlg*, *ID*, *size&* [,*cmd&*] [AT *item&*]

A separator is added to this TOOLBAR. It separates two buttons by the number of pixels specified in *size&*. It may be used to separate and distinguish two adjacent button groups (%tbstyle_group), or to just enhance the visual appearance. If the optional *cmd&* parameter is included, it's a unique numeric identifier for this separator. Of course, a separator can't be pressed like a button, so it doesn't literally allow a command to be sent. However, it may be used later with a BYCMD option in TOOLBAR DELETE, TOOLBAR SET STATE, etc. If the "AT *item&*" clause is included, the separator is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

TOOLBAR DELETE BUTTON *hDlg*, *ID*, [BYCMD] *item&*

A BUTTON or SEPARATOR, specified by *item&*, is deleted from the TOOLBAR. The parameter *item&* may be positional, or it may represent a command id number with BYCMD.

TOOLBAR GET COUNT *hDlg*, *ID* to *datav&*

The number of buttons (and separators) on the TOOLBAR is retrieved and assigned to the long integer variable specified by *datav&*.

TOOLBAR GET STATE *hDlg*, *ID*, [BYCMD] *item&* TO *datav&*

The state descriptor bits for a specific button are retrieved and assigned to the variable designated by *datav&*. The parameter *item&* tells which button to check -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits may consist of one or more of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.
%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

TOOLBAR SET IMAGELIST *hDlg*, *ID*, *hLst*, *type&*

The IMAGELIST specified by *hLst* is attached to this TOOLBAR control. The value of *ListType&* specifies the type of IMAGELIST:

0	Default images
1	Disabled images
2	Hot images

The graphical images contained in the IMAGELIST are displayed on the TOOLBAR buttons. Up to three IMAGELIST structures may be attached to each TOOLBAR control. The image to be displayed is determined by the specification made in TOOLBAR ADD BUTTON, and the current state of the button. When the TOOLBAR control is destroyed, any attached IMAGELIST is automatically destroyed.

TOOLBAR SET STATE *hDlg*, *ID*, [BYCMD] *item&*, *state&*

The state descriptor bits for the specified button are applied from the expression *state&*. The parameter *item&* tells which button to set -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits *state&* may consist of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.
%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

TOOLBAR GET COUNT statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

TOOLBAR statement IMPROVED

Purpose A ToolBar control contains one or more buttons which act as shortcuts to menu items. The TOOLBAR statement is used to manipulate a TOOLBAR control.

Syntax

```
TOOLBAR ADD BUTTON hDlg, ID, image&, cmd&, style&, text$ [AT item&] [CALL callback]
TOOLBAR ADD SEPARATOR hDlg, ID, size& [,cmd&] [AT item&]
TOOLBAR DELETE BUTTON hDlg, id&, [BYCMD] item&
TOOLBAR GET STATE hDlg, ID, [BYCMD] item& TO datav&
TOOLBAR GET COUNT hDlg, ID TO datav&
TOOLBAR SET IMAGELIST hDlg, ID, hLst, ListType&
TOOLBAR SET STATE hDlg, ID, [BYCMD] item&, state&
```

hDlg Handle of the dialog that owns the ToolBar.

hLst Handle of the ImageList to be used for graphical items.

id& The control identifier assigned with CONTROL ADD TOOLBAR.

cmd& Command id number associated with this button.

image& Image number selected (1=first, 2=second, etc.)

item& A data item number. First=1, second=2...

size& Size of the item expressed in pixels.

state& A state descriptor to define specific attributes.

style& Style descriptor bits for this button.

text$ A text

to be displayed on this button.

type& A type descriptor to define specific attributes.

callback A callback function which receives messages for the control.

datav& A long integer variable to which result data is assigned.

txtv$ A string variable to which result text is assigned.

Remarks A TOOLBAR control contains one or more buttons, each of which normally corresponds to a menu item. It is generally placed at the top of the client area of a dialog. When the user "presses" a tool bar button, the program reacts in the same way as if the command had been selected from a menu. It simply acts as a shortcut to common menu commands.

In each of the following descriptions, the TOOLBAR is referenced by the dialog handle (*hDlg*) and id&. In some cases a specific button is chosen with the *item&* parameter. If the BYCMD option is included, *item&* specifies the command id number of the button to be used. If not, *item&* describes the button by its position on the TOOLBAR. Since separators are considered to be a special class of button by the operating system, they must be counted when you calculate a position item number. Positions are always indexed to one (1=first, 2=second, and so on).

TOOLBAR ADD BUTTON *hDlg*, *ID*, *image&*, *cmd&*, *style&*, *text$* [AT *item&*] [CALL *callback*]

A button is added to this TOOLBAR. The image to be displayed is selected from the attached IMAGELIST based upon the parameter *image&* (1=first, 2=second, etc.). The *cmd&* parameter specifies the command id number to be executed (with %WM_COMMAND) when the button is pressed. The *style&* parameter describes the style of the button from the following most often used attributes:

%BTNS_AUTOSIZE The width of the button is calculated by the system, based upon the text and the image.

%BTNS_BUTTON	The button behaves like a standard push button.
%BTNS_CHECK	The button is dual-state which toggles between the pressed and nonpressed state each time it's clicked.
%BTNS_GROUP	Defines a group of buttons. When combined with the check style, it creates a button that stays pressed until another button in the group is pressed. This is similar to an option button or radio button.
%BTNS_CHECKGROUP	A combination of check and group styles.
%BTNS_DROPDOWN	Creates a drop-down style button that can display a list when clicked. Drop-down buttons send a %TBN_DROPDOWN notification instead of %WM_COMMAND.
%BTNS_NOPREFIX	The button text will not have an accelerator prefix associated with it.

The *text$* parameter specifies the text to be displayed on the button.

If the optional "AT *item&*" clause is included, the button is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

If the optional "CALL *callback*" clause is included, it specifies the name of a Callback Function that receives %WM_COMMAND messages when the button is clicked. If not specified, these command messages are sent to the dialog callback specified in

. Message routing by button allows you to easily determine which button generated the event.

If the Callback Function processes a message, it should return TRUE (non-zero) to prevent the message being passed unnecessarily to the dialog callback (if one exists). The dialog callback should also return TRUE if the notification message is processed by that Callback Function. Otherwise, the DDT engine processes unhandled messages.

TOOLBAR ADD SEPARATOR *hDlg*, *ID*, *size&* [,*cmd&*] [AT *item&*]

A separator is added to this TOOLBAR. It separates two buttons by the number of pixels specified in *size&*. It may be used to separate and distinguish two adjacent button groups (%tbstyle_group), or to just enhance the visual appearance. If the optional *cmd&* parameter is included, it's a unique numeric identifier for this separator. Of course, a separator can't be pressed like a button, so it doesn't literally allow a command to be sent. However, it may be used later with a BYCMD option in TOOLBAR DELETE, TOOLBAR SET STATE, etc. If the "AT *item&*" clause is included, the separator is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

TOOLBAR DELETE BUTTON *hDlg*, *ID*, [BYCMD] *item&*

A BUTTON or SEPARATOR, specified by *item&*, is deleted from the TOOLBAR. The parameter *item&* may be positional, or it may represent a command id number with BYCMD.

TOOLBAR GET COUNT *hDlg*, *ID* to *datav&*

The number of buttons (and separators) on the TOOLBAR is retrieved and assigned to the long integer variable specified by *datav&*.

TOOLBAR GET STATE *hDlg*, *ID*, [BYCMD] *item&* TO *datav&*

The state descriptor bits for a specific button are retrieved and assigned to the variable designated by *datav&*. The parameter *item&* tells which button to check -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits may consist of one or more of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.
%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

TOOLBAR SET IMAGELIST *hDlg*, *ID*, *hLst*, *type&*

The IMAGELIST specified by *hLst* is attached to this TOOLBAR control. The value of *ListType&* specifies the type of IMAGELIST:

0	Default images
1	Disabled images
2	Hot images

The graphical images contained in the IMAGELIST are displayed on the TOOLBAR buttons. Up to three IMAGELIST structures may be attached to each TOOLBAR control. The image to be displayed is determined by the specification made in TOOLBAR ADD BUTTON, and the current state of the button. When the TOOLBAR control is destroyed, any attached IMAGELIST is automatically destroyed.

TOOLBAR SET STATE *hDlg*, *ID*, [BYCMD] *item&*, *state&*

The state descriptor bits for the specified button are applied from the expression *state&*. The parameter *item&* tells which button to set -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits *state&* may consist of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.
%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

TOOLBAR GET STATE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

TOOLBAR statement IMPROVED

Purpose A ToolBar control contains one or more buttons which act as shortcuts to menu items. The TOOLBAR statement is used to manipulate a TOOLBAR control.

Syntax

```
TOOLBAR ADD BUTTON hDlg, ID, image&, cmd&, style&, text$ [AT item&] [CALL callback]
TOOLBAR ADD SEPARATOR hDlg, ID, size& [,cmd&] [AT item&]
TOOLBAR DELETE BUTTON hDlg, id&, [BYCMD] item&
TOOLBAR GET STATE hDlg, ID, [BYCMD] item& TO datav&
TOOLBAR GET COUNT hDlg, ID TO datav&
TOOLBAR SET IMAGELIST hDlg, ID, hLst, ListType&
TOOLBAR SET STATE hDlg, ID, [BYCMD] item&, state&
```

hDlg	Handle of the dialog that owns the ToolBar.
hLst	Handle of the ImageList to be used for graphical items.
id&	The control identifier assigned with CONTROL ADD TOOLBAR.
cmd&	Command id number associated with this button.
image&	Image number selected (1=first, 2=second, etc.)
item&	A data item number. First=1, second=2...
size&	Size of the item expressed in pixels.
state&	A state descriptor to define specific attributes.
style&	Style descriptor bits for this button.
text$	A text to be displayed on this button.
type&	A type descriptor to define specific attributes.
callback	A callback function which receives messages for the control.
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result text is assigned.

Remarks

A TOOLBAR control contains one or more buttons, each of which normally corresponds to a menu item. It is generally placed at the top of the client area of a dialog. When the user "presses" a tool bar button, the program reacts in the same way as if the command had been selected from a menu. It simply acts as a shortcut to common menu commands.

In each of the following descriptions, the TOOLBAR is referenced by the dialog handle (*hDlg*) and id&. In some cases a specific button is chosen with the *item&* parameter. If the BYCMD option is included, *item&* specifies the command id number of the button to be used. If not, *item&* describes the button by its position on the TOOLBAR. Since separators are considered to be a special class of button by the operating system, they must be counted when you calculate a position item number. Positions are always indexed to one (1=first, 2=second, and so on).

TOOLBAR ADD BUTTON *hDlg*, *ID*, *image&*, *cmd&*, *style&*, *text$* [AT *item&*] [CALL *callback*]

A button is added to this TOOLBAR. The image to be displayed is selected from the attached IMAGELIST based upon the parameter *image&* (1=first, 2=second, etc.). The *cmd&* parameter specifies the command id number to be executed (with % WM_COMMAND) when the button is pressed. The *style&* parameter describes the style of the button from the following most often used attributes:

%BTNS_AUTOSIZE	The width of the button is calculated by the system, based upon the text and the image.
%BTNS_BUTTON	The button behaves like a standard push button.
%BTNS_CHECK	The button is dual-state which toggles between the pressed and nonpressed state each time it's clicked.
%BTNS_GROUP	Defines a group of buttons. When combined with the check style, it creates a button that stays pressed until another

	button in the group is pressed. This is similar to an option button or radio button.
%BTNS_CHECKGROUP	A combination of check and group styles.
%BTNS_DROPDOWN	Creates a drop-down style button that can display a list when clicked. Drop-down buttons send a %TBN_DROPDOWN notification instead of %WM_COMMAND.
%BTNS_NOPREFIX	The button text will not have an accelerator prefix associated with it.

The *text$* parameter specifies the text to be displayed on the button.

If the optional "AT *item&*" clause is included, the button is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

If the optional "CALL *callback*" clause is included, it specifies the name of a Callback Function that receives %WM_COMMAND messages when the button is clicked. If not specified, these command messages are sent to the dialog callback specified in

. Message routing by button allows you to easily determine which button generated the event.

If the Callback Function processes a message, it should return TRUE (non-zero) to prevent the message being passed unnecessarily to the dialog callback (if one exists). The dialog callback should also return TRUE if the notification message is processed by that Callback Function. Otherwise, the DDT engine processes unhandled messages.

TOOLBAR ADD SEPARATOR *hDlg*, *ID*, *size&* [,*cmd&*] [AT *item&*]

A separator is added to this TOOLBAR. It separates two buttons by the number of pixels specified in *size&*. It may be used to separate and distinguish two adjacent button groups (%tbstyle_group), or to just enhance the visual appearance. If the optional *cmd&* parameter is included, it's a unique numeric identifier for this separator. Of course, a separator can't be pressed like a button, so it doesn't literally allow a command to be sent. However, it may be used later with a BYCMD option in TOOLBAR DELETE, TOOLBAR SET STATE, etc. If the "AT *item&*" clause is included, the separator is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

TOOLBAR DELETE BUTTON *hDlg*, *ID*, [BYCMD] *item&*

A BUTTON or SEPARATOR, specified by *item&*, is deleted from the TOOLBAR. The parameter *item&* may be positional, or it may represent a command id number with BYCMD.

TOOLBAR GET COUNT *hDlg*, *ID* to *datav&*

The number of buttons (and separators) on the TOOLBAR is retrieved and assigned to the long integer variable specified by *datav&*.

TOOLBAR GET STATE *hDlg*, *ID*, [BYCMD] *item&* TO *datav&*

The state descriptor bits for a specific button are retrieved and assigned to the variable designated by *datav&*. The parameter *item&* tells which button to check -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits may consist of one or more of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.

%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

TOOLBAR SET IMAGELIST *hDlg, ID, hLst, type&*

The IMAGELIST specified by *hLst* is attached to this TOOLBAR control. The value of *ListType&* specifies the type of IMAGELIST:

0	Default images
1	Disabled images
2	Hot images

The graphical images contained in the IMAGELIST are displayed on the TOOLBAR buttons. Up to three IMAGELIST structures may be attached to each TOOLBAR control. The image to be displayed is determined by the specification made in TOOLBAR ADD BUTTON, and the current state of the button. When the TOOLBAR control is destroyed, any attached IMAGELIST is automatically destroyed.

TOOLBAR SET STATE *hDlg, ID*, [BYCMD] *item&, state&*

The state descriptor bits for the specified button are applied from the expression *state&*. The parameter *item&* tells which button to set -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits *state&* may consist of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.
%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

TOOLBAR SET IMAGELIST statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

TOOLBAR statement IMPROVED

Purpose A ToolBar control contains one or more buttons which act as shortcuts to menu items. The TOOLBAR statement is used to manipulate a TOOLBAR control.

Syntax

```
TOOLBAR ADD BUTTON hDlg, ID, image&, cmd&, style&, text$ [AT item&] [CALL callback]
TOOLBAR ADD SEPARATOR hDlg, ID, size& [,cmd&] [AT item&]
TOOLBAR DELETE BUTTON hDlg, id&, [BYCMD] item&
TOOLBAR GET STATE hDlg, ID, [BYCMD] item& TO datav&
TOOLBAR GET COUNT hDlg, ID TO datav&
```

TOOLBAR SET IMAGELIST *hDlg, ID, hLst, ListType&*
TOOLBAR SET STATE *hDlg, ID,* [BYCMD] *item&, state&*

hDlg	Handle of the dialog that owns the ToolBar.
hLst	Handle of the ImageList to be used for graphical items.
id&	The control identifier assigned with CONTROL ADD TOOLBAR.
cmd&	Command id number associated with this button.
image&	Image number selected (1=first, 2=second, etc.)
item&	A data item number. First=1, second=2...
size&	Size of the item expressed in pixels.
state&	A state descriptor to define specific attributes.
style&	Style descriptor bits for this button.
text$	A text to be displayed on this button.
type&	A type descriptor to define specific attributes.
callback	A callback function which receives messages for the control.
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result text is assigned.

Remarks

A TOOLBAR control contains one or more buttons, each of which normally corresponds to a menu item. It is generally placed at the top of the client area of a dialog. When the user "presses" a tool bar button, the program reacts in the same way as if the command had been selected from a menu. It simply acts as a shortcut to common menu commands.

In each of the following descriptions, the TOOLBAR is referenced by the dialog handle (*hDlg*) and id&. In some cases a specific button is chosen with the *item&* parameter. If the BYCMD option is included, *item&* specifies the command id number of the button to be used. If not, *item&* describes the button by its position on the TOOLBAR. Since separators are considered to be a special class of button by the operating system, they must be counted when you calculate a position item number. Positions are always indexed to one (1=first, 2=second, and so on).

TOOLBAR ADD BUTTON *hDlg, ID, image&, cmd&, style&, text$* [AT *item&*] [CALL *callback*]

A button is added to this TOOLBAR. The image to be displayed is selected from the attached IMAGELIST based upon the parameter *image&* (1=first, 2=second, etc.). The *cmd&* parameter specifies the command id number to be executed (with %WM_COMMAND) when the button is pressed. The *style&* parameter describes the style of the button from the following most often used attributes:

%BTNS_AUTOSIZE	The width of the button is calculated by the system, based upon the text and the image.
%BTNS_BUTTON	The button behaves like a standard push button.
%BTNS_CHECK	The button is dual-state which toggles between the pressed and nonpressed state each time it's clicked.
%BTNS_GROUP	Defines a group of buttons. When combined with the check style, it creates a button that stays pressed until another button in the group is pressed. This is similar to an option button or radio button.
%BTNS_CHECKGROUP	A combination of check and group styles.
%	Creates a drop-down style button that can display a list

BTNS_DROPDOWN	when clicked. Drop-down buttons send a %TBN_DROPDOWN notification instead of %WM_COMMAND.
%BTNS_NOPREFIX	The button text will not have an accelerator prefix associated with it.

The *text$* parameter specifies the text to be displayed on the button.

If the optional "AT *item&*" clause is included, the button is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

If the optional "CALL *callback*" clause is included, it specifies the name of a Callback Function that receives %WM_COMMAND messages when the button is clicked. If not specified, these command messages are sent to the dialog callback specified in

. Message routing by button allows you to easily determine which button generated the event.

If the Callback Function processes a message, it should return TRUE (non-zero) to prevent the message being passed unnecessarily to the dialog callback (if one exists). The dialog callback should also return TRUE if the notification message is processed by that Callback Function. Otherwise, the DDT engine processes unhandled messages.

TOOLBAR ADD SEPARATOR *hDlg*, *ID*, *size&* [,*cmd&*] [AT *item&*]

A separator is added to this TOOLBAR. It separates two buttons by the number of pixels specified in *size&*. It may be used to separate and distinguish two adjacent button groups (%tbstyle_group), or to just enhance the visual appearance. If the optional *cmd&* parameter is included, it's a unique numeric identifier for this separator. Of course, a separator can't be pressed like a button, so it doesn't literally allow a command to be sent. However, it may be used later with a BYCMD option in TOOLBAR DELETE, TOOLBAR SET STATE, etc. If the "AT *item&*" clause is included, the separator is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

TOOLBAR DELETE BUTTON *hDlg*, *ID*, [BYCMD] *item&*

A BUTTON or SEPARATOR, specified by *item&*, is deleted from the TOOLBAR. The parameter *item&* may be positional, or it may represent a command id number with BYCMD.

TOOLBAR GET COUNT *hDlg*, *ID* to *datav&*

The number of buttons (and separators) on the TOOLBAR is retrieved and assigned to the long integer variable specified by *datav&*.

TOOLBAR GET STATE *hDlg*, *ID*, [BYCMD] *item&* TO *datav&*

The state descriptor bits for a specific button are retrieved and assigned to the variable designated by *datav&*. The parameter *item&* tells which button to check -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits may consist of one or more of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.
%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

TOOLBAR SET IMAGELIST *hDlg*, *ID*, *hLst*, *type&*

The IMAGELIST specified by *hLst* is attached to this TOOLBAR control. The value of *ListType&* specifies the type of IMAGELIST:

0	Default images
1	Disabled images
2	Hot images

The graphical images contained in the IMAGELIST are displayed on the TOOLBAR buttons. Up to three IMAGELIST structures may be attached to each TOOLBAR control. The image to be displayed is determined by the specification made in TOOLBAR ADD BUTTON, and the current state of the button. When the TOOLBAR control is destroyed, any attached IMAGELIST is automatically destroyed.

TOOLBAR SET STATE *hDlg*, *ID*, [BYCMD] *item&*, *state&*

The state descriptor bits for the specified button are applied from the expression *state&*. The parameter *item&* tells which button to set -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits *state&* may consist of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.
%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

Example

TOOLBAR statement IMPROVED

Purpose A ToolBar control contains one or more buttons which act as shortcuts to menu items. The TOOLBAR statement is used to manipulate a TOOLBAR control.

Syntax

```
TOOLBAR ADD BUTTON hDlg, ID, image&, cmd&, style&, text$ [AT item&] [CALL callback]
TOOLBAR ADD SEPARATOR hDlg, ID, size& [,cmd&] [AT item&]
TOOLBAR DELETE BUTTON hDlg, id&, [BYCMD] item&
TOOLBAR GET STATE hDlg, ID, [BYCMD] item& TO datav&
TOOLBAR GET COUNT hDlg, ID TO datav&
TOOLBAR SET IMAGELIST hDlg, ID, hLst, ListType&
TOOLBAR SET STATE hDlg, ID, [BYCMD] item&, state&
```

hDlg Handle of the dialog that owns the ToolBar.

hLst Handle of the ImageList to be used for graphical items.

id&	The control identifier assigned with CONTROL ADD TOOLBAR.
cmd&	Command id number associated with this button.
image&	Image number selected (1=first, 2=second, etc.)
item&	A data item number. First=1, second=2...
size&	Size of the item expressed in pixels.
state&	A state descriptor to define specific attributes.
style&	Style descriptor bits for this button.
text$	A text to be displayed on this button.
type&	A type descriptor to define specific attributes.
callback	A callback function which receives messages for the control.
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result text is assigned.

Remarks

A TOOLBAR control contains one or more buttons, each of which normally corresponds to a menu item. It is generally placed at the top of the client area of a dialog. When the user "presses" a tool bar button, the program reacts in the same way as if the command had been selected from a menu. It simply acts as a shortcut to common menu commands.

In each of the following descriptions, the TOOLBAR is referenced by the dialog handle (*hDlg*) and id&. In some cases a specific button is chosen with the *item&* parameter. If the BYCMD option is included, *item&* specifies the command id number of the button to be used. If not, *item&* describes the button by its position on the TOOLBAR. Since separators are considered to be a special class of button by the operating system, they must be counted when you calculate a position item number. Positions are always indexed to one (1=first, 2=second, and so on).

TOOLBAR ADD BUTTON *hDlg*, *ID*, *image&*, *cmd&*, *style&*, *text$* [AT *item&*] [CALL *callback*]

A button is added to this TOOLBAR. The image to be displayed is selected from the attached IMAGELIST based upon the parameter *image&* (1=first, 2=second, etc.). The *cmd&* parameter specifies the command id number to be executed (with %WM_COMMAND) when the button is pressed. The *style&* parameter describes the style of the button from the following most often used attributes:

%BTNS_AUTOSIZE	The width of the button is calculated by the system, based upon the text and the image.
%BTNS_BUTTON	The button behaves like a standard push button.
%BTNS_CHECK	The button is dual-state which toggles between the pressed and nonpressed state each time it's clicked.
%BTNS_GROUP	Defines a group of buttons. When combined with the check style, it creates a button that stays pressed until another button in the group is pressed. This is similar to an option button or radio button.
%BTNS_CHECKGROUP	A combination of check and group styles.
%BTNS_DROPDOWN	Creates a drop-down style button that can display a list when clicked. Drop-down buttons send a %TBN_DROPDOWN notification instead of %WM_COMMAND.
%BTNS_NOPREFIX	The button text will not have an accelerator prefix associated with it.

The *text$* parameter specifies the text to be displayed on the button.

If the optional "AT *item&*" clause is included, the button is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

If the optional "CALL *callback*" clause is included, it specifies the name of a Callback Function that receives %WM_COMMAND messages when the button is clicked. If not specified, these command messages are sent to the dialog callback specified in

. Message routing by button allows you to easily determine which button generated the event.

If the Callback Function processes a message, it should return TRUE (non-zero) to prevent the message being passed unnecessarily to the dialog callback (if one exists). The dialog callback should also return TRUE if the notification message is processed by that Callback Function. Otherwise, the DDT engine processes unhandled messages.

TOOLBAR ADD SEPARATOR *hDlg*, *ID*, *size&* [,*cmd&*] [AT *item&*]

A separator is added to this TOOLBAR. It separates two buttons by the number of pixels specified in *size&*. It may be used to separate and distinguish two adjacent button groups (%tbstyle_group), or to just enhance the visual appearance. If the optional *cmd&* parameter is included, it's a unique numeric identifier for this separator. Of course, a separator can't be pressed like a button, so it doesn't literally allow a command to be sent. However, it may be used later with a BYCMD option in TOOLBAR DELETE, TOOLBAR SET STATE, etc. If the "AT *item&*" clause is included, the separator is inserted at the designated position (1=first, 2=second, etc.). Otherwise, it is added to the end of the list.

TOOLBAR DELETE BUTTON *hDlg*, *ID*, [BYCMD] *item&*

A BUTTON or SEPARATOR, specified by *item&*, is deleted from the TOOLBAR. The parameter *item&* may be positional, or it may represent a command id number with BYCMD.

TOOLBAR GET COUNT *hDlg*, *ID* to *datav&*

The number of buttons (and separators) on the TOOLBAR is retrieved and assigned to the long integer variable specified by *datav&*.

TOOLBAR GET STATE *hDlg*, *ID*, [BYCMD] *item&* TO *datav&*

The state descriptor bits for a specific button are retrieved and assigned to the variable designated by *datav&*. The parameter *item&* tells which button to check -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits may consist of one or more of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.
%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

TOOLBAR SET IMAGELIST *hDlg*, *ID*, *hLst*, *type&*

The IMAGELIST specified by *hLst* is attached to this TOOLBAR control. The value of *ListType&* specifies the type of IMAGELIST:

0	Default images
1	Disabled images
2	Hot images

The graphical images contained in the IMAGELIST are displayed on the TOOLBAR buttons. Up to three IMAGELIST structures may be attached to each TOOLBAR control. The image to be displayed is determined by the specification made in TOOLBAR ADD BUTTON, and the current state of the button. When the TOOLBAR control is destroyed, any attached IMAGELIST is automatically destroyed.

TOOLBAR SET STATE *hDlg*, *ID*, [BYCMD] *item&*, *state&*

The state descriptor bits for the specified button are applied from the expression *state&*. The parameter *item&* tells which button to set -- it may be positional, or it may be the command id number when used with BYCMD. The descriptor bits *state&* may consist of:

%TBSTATE_DISABLED	The button is disabled and grayed. (value=0)
%TBSTATE_CHECKED	The button is checked.
%TBSTATE_PRESSED	The button is pressed.
%TBSTATE_ENABLED	The button is enabled.
%TBSTATE_HIDDEN	The button is hidden.
%TBSTATE_INDETERMINATE	The button is indeterminate and grayed.
%TBSTATE_MARKED	The button is highlighted.

TRACE statement

TRACE statement

Purpose Capture a representation of the precise flow of execution in a module.

Syntax

```
TRACE NEW fname$
TRACE ON
TRACE PRINT string_expr
TRACE OFF
TRACE CLOSE
```

Remarks The TRACE statement is used to generate a *trace file* detailing program flow as execution passes through Labels, plus entry and exit of all Subs, Functions, Methods, and Properties, along with details of passed parameters, etc. All trace details are written to a named disk file *fname$*.

TRACE also logs PowerBASIC run-time errors as they occur, to assist with locating program errors. TRACE can be dynamically started and stopped with the TRACE ON and TRACE OFF statements to enable the programmer to check specific portions of a program without generating volumes of irrelevant trace data.

The five general forms of the TRACE statement are described as follow:

TRACE NEW *fname$*

TRACE NEW causes a standard sequential *trace file* (of the specified file name *fname$*) to be created, deleting any previous file of the same name.

`TRACE ON`

When a subsequent TRACE ON is then executed, PowerBASIC begins to write pertinent trace information to the trace file. It will contain a chronological list of every call to an internal procedure, the associated parameter values, and the point at which it was exited. Further, it will list a label name each time that program execution flows through the label position.

In a test or debugging situation, TRACE, CALLSTK, and CALLSTK$ allow you to easily answer that age-old programming question, "How did I get here?". TRACE details the entry and exit of every procedure in your program, while CALLSTK simply lists the stack frames that exist above the current level. TRACE is particularly valuable in pinpointing the area of a program where a fatal machine crash occurs.

TRACE PRINT *string_expr*

TRACE PRINT writes the value of *string_expr* to the trace file. It can be used to record the value of important variables or other information of importance.

TRACE OFF

TRACE OFF temporarily stops output to the trace file. The trace can be subsequently restarted with another TRACE ON statement. An implied TRACE OFF is performed when you exit the procedure in which the current TRACE ON was executed.

TRACE CLOSE

TRACE CLOSE permanently detaches the trace file from the stream of trace data.

The TRACE statement can easily create a huge trace file, so caution must be exercised. Use TRACE ON at the lowest procedure level possible, to keep the output size within reason.

If PBMAIN contains TRACE NEW and TRACE ON statements, and subsequently calls SUB AAA(x&), which in turn calls SUB BBB(y&,a$), which then calls SUB CCC(z&), which encounters a run-time error 5, the trace file might look something like this:

```
Trace Begins...
 AAA(3)
  BBB(4,string data)
   CCC(5)
   TRACE PRINT printed this user data from CCC()
   ERROR 151 was generated in this thread
   CCC Exit
  BBB Exit
 AAA Exit
```

Numeric parameters are displayed in decimal, while pointer and array parameters display a decimal representation of the offset of the target value.

Restrictions

TRACE can be invaluable during debugging, but it generates substantial additional code that should be avoided in the final release version of an application. If the source code contains #TOOLS OFF, all TRACE statements which remain in the program are ignored by the compiler, and the parameters and expressions are excluded from the compiled program.

To conserve memory requirements in the code, long labels are truncated to 13 characters; however, procedure names are not truncated.

The TRACE statement is "Thread-Aware", displaying only Sub, Function, Method, Property, or Label details from the thread in which it was executed. You can execute TRACE multiple times, or even in multiple concurrent threads. However, you must use caution to ensure that each thread uses a unique name for its own trace file.

See also

#TOOLS, CALLSTK, CALLSTK$, CALLSTKCOUNT, FUNCNAME$, PROFILE

Example

```
#TOOLS ON
FUNCTION PBMAIN
  TRACE NEW "tracelog.txt"
  TRACE ON
  x& = 3
  CALL AAA(x&)
  TRACE OFF
  TRACE CLOSE
END FUNCTION

SUB AAA(x&)
  INCR x&
  CALL BBB(x&,"string data")
```

```
  ' More code
END SUB

SUB BBB(y&,a$)
  INCR y&
  CALL CCC(y&)
END SUB

SUB CCC(z&)
  TRACE PRINT "TRACE PRINT printed this " + _
    "user data from " + FUNCNAME$ + "()"
  ERROR 151 ' Trigger a run-time error
END SUB
```

TREEVIEW DELETE statement

Keyword Template

Purpose

Syntax

Remarks

Example

TREEVIEW statement

Purpose

A TreeView control displays a set of data items with a parent-child relationship between the items. This creates a hierarchical list of data which can have any number of levels. Each item displays an optional image and a text

. Each time you add an item, you must specify its relationship to existing data items.

Syntax

TREEVIEW DELETE ***hDlg, id&, hItem***
TREEVIEW GET BOLD ***hDlg, id&, hItem*** **TO** ***datav&***
TREEVIEW GET CHECK ***hDlg, id&, hItem*** **TO** ***datav&***
TREEVIEW GET CHILD ***hDlg, id&, hItem*** **TO** ***datav&***
TREEVIEW GET COUNT ***hDlg, id&*** **TO** ***datav&***
TREEVIEW GET EXPANDED ***hDlg, id&, hItem*** **TO** ***datav&***
TREEVIEW GET NEXT ***hDlg, id&, hItem*** **TO** ***datav&***
TREEVIEW GET PARENT ***hDlg, id&, hItem*** **TO** ***datav&***
TREEVIEW GET PREVIOUS ***hDlg, id&, hItem*** **TO** ***datav&***
TREEVIEW GET ROOT ***hDlg, id&*** **TO** ***datav&***
TREEVIEW GET SELECT ***hDlg, id&*** **TO** ***datav&***
TREEVIEW GET TEXT ***hDlg, id&, hItem*** **TO** ***txtv$***
TREEVIEW GET USER ***hDlg, id&, hItem*** **TO** ***datav&***
TREEVIEW INSERT ITEM ***hDlg, id&, hPrnt, hIAftr, image&, simage&, txt$*** **TO** ***hItem***
TREEVIEW RESET ***hDlg, id&***
TREEVIEW SELECT ***hDlg, id&, hItem***
TREEVIEW SET BOLD ***hDlg, id&, hItem, flag&***
TREEVIEW SET CHECK ***hDlg, id&, hItem, flag&***
TREEVIEW SET EXPANDED ***hDlg, id&, hItem, flag&***
TREEVIEW SET IMAGELIST ***hDlg, id&, hLst***
TREEVIEW SET TEXT ***hDlg, id&, hItem, txt$***
TREEVIEW SET USER ***hDlg, id&, hItem, NumExpr***
TREEVIEW UNSELECT ***hDlg, id&***

hDlg	Handle of the dialog that owns the Treeview.
id&	The control identifier assigned with CONTROL ADD TREEVIEW.
hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg*, *id&*, *hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg*, *id&*, *hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg, id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg, id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg, id&, hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg, id&, hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg, id&, hPrnt, hIAftr, image&, selimage&, txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg, id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg, id&, hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg, id&, hItem, flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg, id&, hItem, flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg, id&, hItem, flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg, id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg, id&, hItem, txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg, id&, hItem, NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg, id&*

All items in the TREEVIEW control are set to an unselected state.

Example

TREEVIEW statement

Purpose A TreeView control displays a set of data items with a parent-child relationship between the items. This creates a hierarchical list of data which can have any number of levels. Each item displays an optional image and a text

. Each time you add an item, you must specify its relationship to existing data items.

Syntax

```
TREEVIEW DELETE hDlg, id&, hItem
TREEVIEW GET BOLD hDlg, id&, hItem TO datav&
TREEVIEW GET CHECK hDlg, id&, hItem TO datav&
TREEVIEW GET CHILD hDlg, id&, hItem TO datav&
TREEVIEW GET COUNT hDlg, id& TO datav&
TREEVIEW GET EXPANDED hDlg, id&, hItem TO datav&
TREEVIEW GET NEXT hDlg, id&, hItem TO datav&
TREEVIEW GET PARENT hDlg, id&, hItem TO datav&
TREEVIEW GET PREVIOUS hDlg, id&, hItem TO datav&
TREEVIEW GET ROOT hDlg, id& TO datav&
TREEVIEW GET SELECT hDlg, id& TO datav&
TREEVIEW GET TEXT hDlg, id&, hItem TO txtv$
TREEVIEW GET USER hDlg, id&, hItem TO datav&
TREEVIEW INSERT ITEM hDlg, id&, hPrnt, hIAftr, image&, simage&, txt$ TO
hItem
TREEVIEW RESET hDlg, id&
TREEVIEW SELECT hDlg, id&, hItem
TREEVIEW SET BOLD hDlg, id&, hItem, flag&
TREEVIEW SET CHECK hDlg, id&, hItem, flag&
TREEVIEW SET EXPANDED hDlg, id&, hItem, flag&
TREEVIEW SET IMAGELIST hDlg, id&, hLst
TREEVIEW SET TEXT hDlg, id&, hItem, txt$
TREEVIEW SET USER hDlg, id&, hItem, NumExpr
TREEVIEW UNSELECT hDlg, id&
```

hDlg	Handle of the dialog that owns the Treeview.
id&	The control identifier assigned with CONTROL ADD TREEVIEW.
hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg*, *id&*, *hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg*, *id&*, *hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hlAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg*, *id&*

All items in the TREEVIEW control are set to an unselected state.

TREEVIEW UNSELECT hDlg, id&
```

hDlg Handle of the dialog that owns the Treeview.

id& The control identifier assigned with CONTROL ADD TREEVIEW.

hItem Handle of a Treeview item, used to uniquely identify the item

datav& A long integer variable to which result data is assigned.

txtv$ A string variable to which result data is assigned.

hPrnt Handle of the parent item to insert the new item under.

hIAftr Handle of the item to insert the new item after.

image& Image index of the new item

simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg*, *id&*, *hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg*, *id&*, *hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg, id&, hItem, txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg, id&, hItem, NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg, id&*

All items in the TREEVIEW control are set to an unselected state.

TREEVIEW UNSELECT hDlg, id&
```

hDlg	Handle of the dialog that owns the Treeview.
id&	The control identifier assigned with CONTROL ADD TREEVIEW.
hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg, id&, hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg, id&, hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg, id&, hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg, id&, hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg, id&, hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg*, *id&*

All items in the TREEVIEW control are set to an unselected state.

Example

TREEVIEW statement

Purpose

A TreeView control displays a set of data items with a parent-child relationship between the items. This creates a hierarchical list of data which can have any number of levels. Each item displays an optional image and a text

. Each time you add an item, you must specify its relationship to existing data items.

Syntax

TREEVIEW DELETE *hDlg, id&, hItem*
TREEVIEW GET BOLD *hDlg, id&, hItem* TO *datav&*
TREEVIEW GET CHECK *hDlg, id&, hItem* TO *datav&*
TREEVIEW GET CHILD *hDlg, id&, hItem* TO *datav&*
TREEVIEW GET COUNT *hDlg, id&* TO *datav&*
TREEVIEW GET EXPANDED *hDlg, id&, hItem* TO *datav&*
TREEVIEW GET NEXT *hDlg, id&, hItem* TO *datav&*
TREEVIEW GET PARENT *hDlg, id&, hItem* TO *datav&*
TREEVIEW GET PREVIOUS *hDlg, id&, hItem* TO *datav&*
TREEVIEW GET ROOT *hDlg, id&* TO *datav&*
TREEVIEW GET SELECT *hDlg, id&* TO *datav&*
TREEVIEW GET TEXT *hDlg, id&, hItem* TO *txtv$*
TREEVIEW GET USER *hDlg, id&, hItem* TO *datav&*
TREEVIEW INSERT ITEM *hDlg, id&, hPrnt, hIAftr, image&, simage&, txt$* TO *hItem*
TREEVIEW RESET *hDlg, id&*
TREEVIEW SELECT *hDlg, id&, hItem*
TREEVIEW SET BOLD *hDlg, id&, hItem, flag&*
TREEVIEW SET CHECK *hDlg, id&, hItem, flag&*
TREEVIEW SET EXPANDED *hDlg, id&, hItem, flag&*
TREEVIEW SET IMAGELIST *hDlg, id&, hLst*
TREEVIEW SET TEXT *hDlg, id&, hItem, txt$*
TREEVIEW SET USER *hDlg, id&, hItem, NumExpr*
TREEVIEW UNSELECT *hDlg, id&*

hDlg — Handle of the dialog that owns the Treeview.

id& — The control identifier assigned with CONTROL ADD TREEVIEW.

hItem — Handle of a Treeview item, used to uniquely identify the item

datav& — A long integer variable to which result data is assigned.

txtv$ — A string variable to which result data is assigned.

hPrnt — Handle of the parent item to insert the new item under.

hIAftr — Handle of the item to insert the new item after.

image& — Image index of the new item

simage& — Selected image index of the new item

txt$ — Text to be displayed for the Treeview item

flag& — A long integer value to define specific attributes

hLst — Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg, id&, hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg, id&, hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg*, *id&*, *hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg, id&*

All items in the TREEVIEW control are set to an unselected state.

TREEVIEW SET TEXT hDlg, id&, hItem, txt$
TREEVIEW SET USER hDlg, id&, hItem, NumExpr
TREEVIEW UNSELECT hDlg, id&
```

hDlg Handle of the dialog that owns the Treeview.

id& The control identifier assigned with CONTROL ADD TREEVIEW.

hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg, id&, hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg, id&, hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg, id&, hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg, id&, hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg, id&, hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or % TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg, id&, hItem, flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg, id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg, id&, hItem, txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg, id&, hItem, NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg, id&*

All items in the TREEVIEW control are set to an unselected state.

```

hDlg	Handle of the dialog that owns the Treeview.
id&	The control identifier assigned with CONTROL ADD TREEVIEW.
hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg, id&, hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg, id&, hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg, id&, hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg, id&, hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items.

If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg, id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg, id&, hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg, id&, hItem, flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg, id&, hItem, flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg, id&, hItem, flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg, id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg, id&, hItem, txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg, id&, hItem, NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg, id&*

All items in the TREEVIEW control are set to an unselected state.

Example

TREEVIEW statement

Purpose	A TreeView control displays a set of data items with a parent-child relationship between the items. This creates a hierarchical list of data which can have any number of levels. Each item displays an optional image and a text . Each time you add an item, you must specify its relationship to existing data items.
Syntax	**TREEVIEW DELETE *hDlg*, *id&*, *hItem*** **TREEVIEW GET BOLD *hDlg*, *id&*, *hItem* TO *datav&*** **TREEVIEW GET CHECK *hDlg*, *id&*, *hItem* TO *datav&*** **TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*** **TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*** **TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*** **TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*** **TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*** **TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*** **TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*** **TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*** **TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*** **TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*** **TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *simage&*, *txt$* TO *hItem*** **TREEVIEW RESET *hDlg*, *id&*** **TREEVIEW SELECT *hDlg*, *id&*, *hItem*** **TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*** **TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*** **TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*** **TREEVIEW SET IMAGELIST *hDlg*, *id&*, *hLst*** **TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*** **TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*** **TREEVIEW UNSELECT *hDlg*, *id&***
hDlg	Handle of the dialog that owns the Treeview.
id&	The control identifier assigned with CONTROL ADD TREEVIEW.
hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg, id&, hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg, id&, hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg, id&, hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg, id&, hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg, id&, hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg, id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg, id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg, id&, hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg, id&, hItem, NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg, id&*

All items in the TREEVIEW control are set to an unselected state.

TREEVIEW SET TEXT hDlg, id&, hItem, txt$
TREEVIEW SET USER hDlg, id&, hItem, NumExpr
TREEVIEW UNSELECT hDlg, id&
```

hDlg	Handle of the dialog that owns the Treeview.
id&	The control identifier assigned with CONTROL ADD TREEVIEW.
hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg, id&, hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg, id&, hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg, id&, hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg, id&, hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg, id&, hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg*, *id&*

All items in the TREEVIEW control are set to an unselected state.

TREEVIEW SET USER *hDlg, id&, hItem, NumExpr*
TREEVIEW UNSELECT *hDlg, id&*

hDlg Handle of the dialog that owns the Treeview.

id& The control identifier assigned with CONTROL ADD TREEVIEW.

hItem Handle of a Treeview item, used to uniquely identify the item

datav& A long integer variable to which result data is assigned.

txtv$ A string variable to which result data is assigned.

hPrnt Handle of the parent item to insert the new item under.

hIAftr Handle of the item to insert the new item after.

image& Image index of the new item

simage& Selected image index of the new item

txt$ Text to be displayed for the Treeview item

flag& A long integer value to define specific attributes

hLst Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg, id&, hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg, id&, hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg, id&, hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT

control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight

user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg, id&*

All items in the TREEVIEW control are set to an unselected state.

Example

TREEVIEW statement

Purpose A TreeView control displays a set of data items with a parent-child relationship between the items. This creates a hierarchical list of data which can have any number of levels. Each item displays an optional image and a text

. Each time you add an item, you must specify its relationship to existing data items.

Syntax

```
TREEVIEW DELETE hDlg, id&, hItem
TREEVIEW GET BOLD hDlg, id&, hItem TO datav&
TREEVIEW GET CHECK hDlg, id&, hItem TO datav&
TREEVIEW GET CHILD hDlg, id&, hItem TO datav&
TREEVIEW GET COUNT hDlg, id& TO datav&
TREEVIEW GET EXPANDED hDlg, id&, hItem TO datav&
TREEVIEW GET NEXT hDlg, id&, hItem TO datav&
TREEVIEW GET PARENT hDlg, id&, hItem TO datav&
TREEVIEW GET PREVIOUS hDlg, id&, hItem TO datav&
TREEVIEW GET ROOT hDlg, id& TO datav&
TREEVIEW GET SELECT hDlg, id& TO datav&
TREEVIEW GET TEXT hDlg, id&, hItem TO txtv$
TREEVIEW GET USER hDlg, id&, hItem TO datav&
TREEVIEW INSERT ITEM hDlg, id&, hPrnt, hIAftr, image&, simage&, txt$ TO
hItem
TREEVIEW RESET hDlg, id&
TREEVIEW SELECT hDlg, id&, hItem
TREEVIEW SET BOLD hDlg, id&, hItem, flag&
TREEVIEW SET CHECK hDlg, id&, hItem, flag&
TREEVIEW SET EXPANDED hDlg, id&, hItem, flag&
TREEVIEW SET IMAGELIST hDlg, id&, hLst
TREEVIEW SET TEXT hDlg, id&, hItem, txt$
TREEVIEW SET USER hDlg, id&, hItem, NumExpr
TREEVIEW UNSELECT hDlg, id&
```

hDlg Handle of the dialog that owns the Treeview.

id& The control identifier assigned with CONTROL ADD TREEVIEW.

hItem Handle of a Treeview item, used to uniquely identify the item

datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg, id&, hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg, id&, hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg, id&, hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg, id&, hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg, id&, hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is

found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg, id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg, id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg, id&, hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg, id&, hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg, id&, hPrnt, hIAftr, image&, selimage&, txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg, id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg, id&, hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg, id&, hItem, flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg, id&, hItem, flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg*, *id&*

All items in the TREEVIEW control are set to an unselected state.

```

hDlg	Handle of the dialog that owns the Treeview.
id&	The control identifier assigned with CONTROL ADD TREEVIEW.
hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg*, *id&*, *hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg*, *id&*, *hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer

variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or % TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the

text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg*, *id&*

All items in the TREEVIEW control are set to an unselected state.

hDlg	Handle of the dialog that owns the Treeview.
id&	The control identifier assigned with CONTROL ADD TREEVIEW.
hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg, id&, hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg, id&, hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg, id&, hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg, id&, hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg, id&, hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg, id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg, id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg, id&, hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg*, *id&*

All items in the TREEVIEW control are set to an unselected state.

TREEVIEW SELECT hDlg, id&, hItem
TREEVIEW SET BOLD hDlg, id&, hItem, flag&
TREEVIEW SET CHECK hDlg, id&, hItem, flag&
```

```
TREEVIEW SET EXPANDED hDlg, id&, hItem, flag&
TREEVIEW SET IMAGELIST hDlg, id&, hLst
TREEVIEW SET TEXT hDlg, id&, hItem, txt$
TREEVIEW SET USER hDlg, id&, hItem, NumExpr
TREEVIEW UNSELECT hDlg, id&
```

hDlg	Handle of the dialog that owns the Treeview.
id&	The control identifier assigned with CONTROL ADD TREEVIEW.
hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg*, *id&*, *hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg*, *id&*, *hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg*, *id&*

All items in the TREEVIEW control are set to an unselected state.

TREEVIEW RESET statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

TREEVIEW statement

Purpose

A TreeView control displays a set of data items with a parent-child relationship between the items. This creates a hierarchical list of data which can have any number of levels. Each item displays an optional image and a text

. Each time you add an item, you must specify its relationship to existing data items.

Syntax

```
TREEVIEW DELETE hDlg, id&, hItem
TREEVIEW GET BOLD hDlg, id&, hItem TO datav&
TREEVIEW GET CHECK hDlg, id&, hItem TO datav&
TREEVIEW GET CHILD hDlg, id&, hItem TO datav&
TREEVIEW GET COUNT hDlg, id& TO datav&
TREEVIEW GET EXPANDED hDlg, id&, hItem TO datav&
TREEVIEW GET NEXT hDlg, id&, hItem TO datav&
TREEVIEW GET PARENT hDlg, id&, hItem TO datav&
TREEVIEW GET PREVIOUS hDlg, id&, hItem TO datav&
TREEVIEW GET ROOT hDlg, id& TO datav&
TREEVIEW GET SELECT hDlg, id& TO datav&
TREEVIEW GET TEXT hDlg, id&, hItem TO txtv$
TREEVIEW GET USER hDlg, id&, hItem TO datav&
TREEVIEW INSERT ITEM hDlg, id&, hPrnt, hIAftr, image&, simage&, txt$ TO
hItem
TREEVIEW RESET hDlg, id&
TREEVIEW SELECT hDlg, id&, hItem
TREEVIEW SET BOLD hDlg, id&, hItem, flag&
TREEVIEW SET CHECK hDlg, id&, hItem, flag&
TREEVIEW SET EXPANDED hDlg, id&, hItem, flag&
TREEVIEW SET IMAGELIST hDlg, id&, hLst
TREEVIEW SET TEXT hDlg, id&, hItem, txt$
TREEVIEW SET USER hDlg, id&, hItem, NumExpr
TREEVIEW UNSELECT hDlg, id&
```

hDlg — Handle of the dialog that owns the Treeview.

id& — The control identifier assigned with CONTROL ADD TREEVIEW.

hItem — Handle of a Treeview item, used to uniquely identify the item

datav& — A long integer variable to which result data is assigned.

txtv$ — A string variable to which result data is assigned.

hPrnt — Handle of the parent item to insert the new item under.

hIAftr — Handle of the item to insert the new item after.

image& — Image index of the new item

simage& — Selected image index of the new item

txt$ — Text to be displayed for the Treeview item

flag& — A long integer value to define specific attributes

hLst — Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg, id&, hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg, id&, hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg, id&, hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT

control offers an additional eight user values which can be accessed with [CONTROL GET USER] and [CONTROL SET USER].

TREEVIEW INSERT ITEM *hDlg, id&, hPrnt, hIAftr, image&, selimage&, txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg, id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg, id&, hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg, id&, hItem, flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg, id&, hItem, flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg, id&, hItem, flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg, id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg, id&, hItem, txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg, id&, hItem, NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight

user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg, id&*

All items in the TREEVIEW control are set to an unselected state.

```

hDlg Handle of the dialog that owns the Treeview.

id& The control identifier assigned with CONTROL ADD TREEVIEW.

hItem Handle of a Treeview item, used to uniquely identify the item

datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg*, *id&*, *hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg*, *id&*, *hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is

found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg, id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg, id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg, id&, hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg, id&, hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg, id&, hPrnt, hIAftr, image&, selimage&, txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg, id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg, id&, hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg, id&, hItem, flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg, id&, hItem, flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg*, *id&*

All items in the TREEVIEW control are set to an unselected state.

TREEVIEW UNSELECT hDlg, id&
```

hDlg Handle of the dialog that owns the Treeview.

id& The control identifier assigned with CONTROL ADD TREEVIEW.

hItem Handle of a Treeview item, used to uniquely identify the item

datav& A long integer variable to which result data is assigned.

txtv$ A string variable to which result data is assigned.

hPrnt Handle of the parent item to insert the new item under.

hIAftr Handle of the item to insert the new item after.

image& Image index of the new item

simage& Selected image index of the new item

txt$ Text to be displayed for the Treeview item

flag& A long integer value to define specific attributes

hLst Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg*, *id&*, *hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg*, *id&*, *hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer

variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or % TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the

text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg, id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg, id&, hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg, id&, hItem, flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg, id&, hItem, flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg, id&, hItem, flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg, id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg, id&, hItem, txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg, id&, hItem, NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg, id&*

All items in the TREEVIEW control are set to an unselected state.

TREEVIEW SET CHECK statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

TREEVIEW statement

Purpose A TreeView control displays a set of data items with a parent-child relationship between the items. This creates a hierarchical list of data which can have any number of levels. Each item displays an optional image and a text

. Each time you add an item, you must specify its relationship to existing data items.

Syntax

```
TREEVIEW DELETE hDlg, id&, hItem
TREEVIEW GET BOLD hDlg, id&, hItem TO datav&
TREEVIEW GET CHECK hDlg, id&, hItem TO datav&
TREEVIEW GET CHILD hDlg, id&, hItem TO datav&
TREEVIEW GET COUNT hDlg, id& TO datav&
TREEVIEW GET EXPANDED hDlg, id&, hItem TO datav&
TREEVIEW GET NEXT hDlg, id&, hItem TO datav&
TREEVIEW GET PARENT hDlg, id&, hItem TO datav&
TREEVIEW GET PREVIOUS hDlg, id&, hItem TO datav&
TREEVIEW GET ROOT hDlg, id& TO datav&
TREEVIEW GET SELECT hDlg, id& TO datav&
TREEVIEW GET TEXT hDlg, id&, hItem TO txtv$
TREEVIEW GET USER hDlg, id&, hItem TO datav&
TREEVIEW INSERT ITEM hDlg, id&, hPrnt, hIAftr, image&, simage&, txt$ TO
hItem
TREEVIEW RESET hDlg, id&
TREEVIEW SELECT hDlg, id&, hItem
TREEVIEW SET BOLD hDlg, id&, hItem, flag&
TREEVIEW SET CHECK hDlg, id&, hItem, flag&
TREEVIEW SET EXPANDED hDlg, id&, hItem, flag&
TREEVIEW SET IMAGELIST hDlg, id&, hLst
TREEVIEW SET TEXT hDlg, id&, hItem, txt$
TREEVIEW SET USER hDlg, id&, hItem, NumExpr
TREEVIEW UNSELECT hDlg, id&
```

hDlg	Handle of the dialog that owns the Treeview.
id&	The control identifier assigned with CONTROL ADD TREEVIEW.
hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg*, *id&*, *hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg*, *id&*, *hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg*, *id&*

All items in the TREEVIEW control are set to an unselected state.

```

hDlg	Handle of the dialog that owns the Treeview.
id&	The control identifier assigned with CONTROL ADD TREEVIEW.
hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg, id&, hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg, id&, hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg, id&, hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg, id&, hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg, id&, hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg, id&, hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg*, *id&*

All items in the TREEVIEW control are set to an unselected state.

TREEVIEW SET TEXT hDlg, id&, hItem, txt$
TREEVIEW SET USER hDlg, id&, hItem, NumExpr
TREEVIEW UNSELECT hDlg, id&
```

hDlg	Handle of the dialog that owns the Treeview.
id&	The control identifier assigned with CONTROL ADD TREEVIEW.
hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg, id&, hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg, id&, hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg, id&, hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT

control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight

user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg*, *id&*

All items in the TREEVIEW control are set to an unselected state.

Example

TREEVIEW statement

Purpose A TreeView control displays a set of data items with a parent-child relationship between the items. This creates a hierarchical list of data which can have any number of levels. Each item displays an optional image and a text

. Each time you add an item, you must specify its relationship to existing data items.

Syntax

```
TREEVIEW DELETE hDlg, id&, hItem
TREEVIEW GET BOLD hDlg, id&, hItem TO datav&
TREEVIEW GET CHECK hDlg, id&, hItem TO datav&
TREEVIEW GET CHILD hDlg, id&, hItem TO datav&
TREEVIEW GET COUNT hDlg, id& TO datav&
TREEVIEW GET EXPANDED hDlg, id&, hItem TO datav&
TREEVIEW GET NEXT hDlg, id&, hItem TO datav&
TREEVIEW GET PARENT hDlg, id&, hItem TO datav&
TREEVIEW GET PREVIOUS hDlg, id&, hItem TO datav&
TREEVIEW GET ROOT hDlg, id& TO datav&
TREEVIEW GET SELECT hDlg, id& TO datav&
TREEVIEW GET TEXT hDlg, id&, hItem TO txtv$
TREEVIEW GET USER hDlg, id&, hItem TO datav&
TREEVIEW INSERT ITEM hDlg, id&, hPrnt, hIAftr, image&, simage&, txt$ TO
hItem
TREEVIEW RESET hDlg, id&
TREEVIEW SELECT hDlg, id&, hItem
TREEVIEW SET BOLD hDlg, id&, hItem, flag&
TREEVIEW SET CHECK hDlg, id&, hItem, flag&
TREEVIEW SET EXPANDED hDlg, id&, hItem, flag&
TREEVIEW SET IMAGELIST hDlg, id&, hLst
TREEVIEW SET TEXT hDlg, id&, hItem, txt$
TREEVIEW SET USER hDlg, id&, hItem, NumExpr
TREEVIEW UNSELECT hDlg, id&
```

hDlg Handle of the dialog that owns the Treeview.

id& The control identifier assigned with CONTROL ADD TREEVIEW.

hItem Handle of a Treeview item, used to uniquely identify the item

datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks **TREEVIEW DELETE *hDlg*, *id&*, *hItem***

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg*, *id&*, *hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg*, *id&*, *hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is

found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg, id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg, id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg, id&, hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg, id&, hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg, id&, hPrnt, hIAftr, image&, selimage&, txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or % TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg, id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg, id&, hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg, id&, hItem, flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg, id&, hItem, flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg*, *id&*

All items in the TREEVIEW control are set to an unselected state.

hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg*, *id&*, *hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg*, *id&*, *hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer

variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the

text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg*, *id&*, *hItem*, *NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg*, *id&*

All items in the TREEVIEW control are set to an unselected state.

hDlg	Handle of the dialog that owns the Treeview.
id&	The control identifier assigned with CONTROL ADD TREEVIEW.
hItem	Handle of a Treeview item, used to uniquely identify the item
datav&	A long integer variable to which result data is assigned.
txtv$	A string variable to which result data is assigned.
hPrnt	Handle of the parent item to insert the new item under.
hIAftr	Handle of the item to insert the new item after.
image&	Image index of the new item
simage&	Selected image index of the new item
txt$	Text to be displayed for the Treeview item
flag&	A long integer value to define specific attributes
hLst	Handle of the ImageList to be used for graphical items.

Remarks

TREEVIEW DELETE *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is deleted from the TREEVIEW control.

TREEVIEW GET BOLD *hDlg*, *id&*, *hItem* TO *datav&*

The bold attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is bold, the value true (-1) is assigned. If not bold, the value false (0) is assigned.

TREEVIEW GET CHECK *hDlg*, *id&*, *hItem* TO *datav&*

The checkmark attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the checkbox is checked, the value true (-1) is assigned. If not checked, the value false (0) is assigned.

TREEVIEW GET CHILD *hDlg*, *id&*, *hItem* TO *datav&*

The parent data item specified by *hItem* is scanned for child data items. If any are found, the handle of the first child is assigned to the variable specified by *datav&*. If none are found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of data items in the TREEVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

TREEVIEW GET EXPANDED *hDlg*, *id&*, *hItem* TO *datav&*

The expanded attribute for the data item *hItem* is retrieved and assigned to the variable *datav&*. If the item is expanded, displaying its child data items, the value true (-1) is assigned. If the item is collapsed, the value false (0) is assigned.

TREEVIEW GET NEXT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the next sibling is assigned to the variable specified by *datav&*. If no next sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PARENT *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for its parent data item. The handle of the parent is assigned to the variable specified by *datav&*. If no parent is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET PREVIOUS *hDlg*, *id&*, *hItem* TO *datav&*

The data item specified by *hItem* is scanned for sibling data items. The handle of the previous sibling is assigned to the variable specified by *datav&*. If no previous sibling is found, the value zero (0) is assigned to *datav&*.

TREEVIEW GET ROOT *hDlg*, *id&* TO *datav&*

The handle of the very first data item (topmost) in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*.

TREEVIEW GET SELECT *hDlg*, *id&* TO *datav&*

The handle of the data item currently selected in the TREEVIEW is retrieved, and assigned to the variable specified by *datav&*. If there is no current selection, the value zero (0) is assigned.

TREEVIEW GET TEXT *hDlg*, *id&*, *hItem* TO *txtv$*

The text of a specific data item (specified by the handle *hItem*) is retrieved from the TREEVIEW control and assigned to the string variable designated by *txtv$*.

TREEVIEW GET USER *hDlg*, *id&*, *hItem* TO *datav&*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed. The returned user value is assigned to the long integer variable specified by *datav&*. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW INSERT ITEM *hDlg*, *id&*, *hPrnt*, *hIAftr*, *image&*, *selimage&*, *txt$* TO *hItem*

A new data item is added to this TREEVIEW control. The parameter *hPrnt* specifies the parent of this item, or zero if item is to be inserted at the root. The parameter *hIAftr* specifies the handle of the item after which this new item is to be inserted, or %TVI_FIRST (at the beginning), %TVI_LAST (at the end), %TVI_SORT (alphabetical order). If an IMAGELIST has been attached, the parameters *image&* and *selimage&* specify which image should be displayed (1=first, 2=second, etc.) for normal and selected items. If no image is needed, the value(s) 0 should be used. The parameter *txt$* designates the text string which should be displayed. If the operation is successful, the handle to the new data item is assigned to the variable designated by *hItem*. If the operation fails, the value zero is assigned to *hItem*.

TREEVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified TREEVIEW control.

TREEVIEW SELECT *hDlg*, *id&*, *hItem*

The data item specified by the handle *hItem* is chosen as selected text for the TREEVIEW control, and the selected text is scrolled into a visible position.

TREEVIEW SET BOLD *hDlg*, *id&*, *hItem*, *flag&*

The bold attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in bold format. If *flag&* is false (zero), it is displayed in normal format.

TREEVIEW SET CHECK *hDlg*, *id&*, *hItem*, *flag&*

The optional checkbox for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is checked. If *flag&* is false (zero), it is unchecked.

TREEVIEW SET EXPANDED *hDlg*, *id&*, *hItem*, *flag&*

The expanded attribute for the data item specified by *hItem* is set based upon the value of the *flag&* parameter. If *flag&* is true (non-zero), it is displayed in expanded format, with its child items visible. If *flag&* is false (zero), it is displayed in collapsed format.

TREEVIEW SET IMAGELIST *hDlg*, *id&*, hLst

The IMAGELIST specified by *hLst* is attached to this TREEVIEW control. The images it contains are displayed as needed with each data item. When the TREEVIEW control is destroyed, any attached IMAGELIST is automatically destroyed.

TREEVIEW SET TEXT *hDlg*, *id&*, *hItem*, *txt$*

The text of a specific data item (specified by the handle *hItem*) is replaced by the text in the string expression *txt$*.

TREEVIEW SET USER *hDlg, id&, hItem, NumExpr*

Each item in a TREEVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with TREEVIEW SET USER, and retrieved with TREEVIEW GET USER. The parameter *hItem* specifies the handle of the user item to be accessed, while *NumExpr* is the user value saved for later retrieval. In addition to these TREEVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

TREEVIEW UNSELECT *hDlg, id&*

All items in the TREEVIEW control are set to an unselected state.

See also Dynamic Dialog Tools, CONTROL ADD TREEVIEW, CONTROL SET COLOR, CONTROL SET FONT, IMAGELIST

TRIM$ function

TRIM$ function IMPROVED

Purpose Removes leading and trailing characters or substrings.

Syntax

```
NewString$ = TRIM$(OldString$ [, [ANY] CharsToTrim$])
NewString$ = TRIM$(NumrExpr [,Digits&])
```

Remarks TRIM$ combines the functionality of LTRIM$ and RTRIM$ into a single function. *OldString$* is the string expression from which to remove characters, and *CharsToTrim$* is the string expression to remove leading and trailing occurrences. If *CharsToTrim$* is not specified, TRIM$ removes leading and trailing spaces.

ANY If the ANY keyword is included, *CharsToTrim$* specifies a list of single characters to be searched for individually, a match on any one of which as a leading or trailing character will cause the character to be removed from the result.

NumrExpr If a numeric expression is provided as the parameter, it is converted to a string (just like STR$), but with no leading or trailing spaces.

digits& The maximum number of significant digits, in the range of 1 to 18. If not included, PowerBASIC supplies a default value of 7 for single precision values, or 16 for more precise values. Use care that *digits&* is large enough to contain the integral part of a number, or scientific notation must be used to estimate it. For example, TRIM$(123.456, 2) returns "1.2E+2", while FORMAT$(123.456, 5) returns the string "123.45".

Restrictions TRIM$ is case sensitive, so capitalization matters.

TRY/END TRY block

TRY/END TRY block

Purpose A structured method of trapping and responding to run-time errors.

Syntax

```
TRY
  [statements]
  [EXIT TRY]
  [statements]
```

```
CATCH
  [error handling statements]
  [EXIT TRY]
  [error handling statements]
[FINALLY
  [statements]
  [EXIT TRY]
  [statements]]
END TRY
```

Remarks

Statements in the TRY section are executed normally. The first time a run-time error occurs, control is transferred to the CATCH section. If no run-time errors are generated in the TRY section, the CATCH section is skipped entirely.

Then, regardless of error status, the FINALLY section is executed, if it is present. Error trapping and control transfer are disabled in the CATCH and FINALLY sections, so you would normally use conventional "

ERR =…" tests to check the success of error-prone operations in those sections.

However, TRY structures can be nested to any level, so it may be desirable to use another TRY block within these clauses.

Restrictions

CATCH is a mandatory section of this structure, although the FINALLY section is optional.

Because of the nesting requirements, the ERR value is local to the TRY structure. Upon exit, the prior ERR value is restored, so be sure to save the value of ERR if it will be needed outside of the TRY structure.

To leave the TRY structure, execution must pass normally through END TRY, or by an EXIT TRY statement. Leaving a TRY block any other way is strongly discouraged because error trapping will remain disabled, and the previous ERR value will not be restored. Future versions of PowerBASIC may disallow such practices.

ON ERROR GOTO is invalid within a TRY structure, but may be used within the same Sub/Function/Method/Property.

#DEBUG ERROR, ERL, ERR, ERRCLEAR, ERROR, Error Overview, ERROR$, Error Trapping, ON ERROR

Example

```
TRY
  OPEN "file.dat" FOR INPUT LOCK READ WRITE AS #1
CATCH
  CALL NotifyUserOfError(ERR)
  EXIT TRY
FINALLY
  CALL UpdateDataBase()
  CLOSE #1
END TRY
```

TXT.CELL method

Keyword Template

Purpose

Syntax

Remarks

See also

Example

TXT pseudo-object New!

Purpose

Displays and inputs text on a specially created TEXT WINDOW. This is similar to a CONSOLE window, with some advantages. Generally speaking, a Text Window is more attractive. But, just like a Console Window, only fixed-width text may be displayed.

Syntax

```
TXT.membername(params)
RetVal = TXT.membername(params)
TXT.membername(params) TO ReturnVariable
```

Remarks

Text Windows offer a specific, but limited capability. They are very easy to implement and use, and they offer an excellent means to produce quick and straightforward programs in text mode.

Text Windows offer an excellent path for the beginning programmer, or for anyone who needs a procedural code model. As the name implies, they display only fixed-width text. Further, only one Text Window may exist at a time. If you need snazzy graphics, more specialized fonts, multiple windows, or a GUI interface, you should look to GRAPHIC WINDOWS and GRAPHIC CONTROLS instead.

Text Window methods are accessed like any other object. The object name TXT is followed by a period separator, and the name of the method or property:

```
TXT.Cell = RowValue&, ColumnVal&
```

Text Window methods which return a value may be used in two forms, a statement with a TO clause, or a function which may be used as a term in an expression:

```
TXT.Row TO RowVar&
RowVar& = TXT.Row
```

The two examples above are functionally identical. The choice is simply a matter of your personal preference. If you use the second form (as a function which returns a value), it can be a term in any expression of any complexity.

Most PowerBASIC functions specify graphic and pixel positions as x,y (the horizontal term first, then the vertical term). However, for compatibility with most current and prior versions of BASIC (PowerBASIC included), the functions which reference text rows and columns name the vertical term first (rows, columns).

Text Windows handle text wrapping and auto-scrolling much like a typical Console Window. When printing exceeds the end of a line, the print position wraps to the first column of the next row. When printing exceeds the last row, the entire page is scrolled to open a new line at the bottom.

In order to use the TXT object successfully, you must use care to first create a Text Window in your program. To do this, you can execute the TXT.WINDOW method.

All Text Windows are stable. They cannot be closed unexpectedly by the user, so there are no surprises when you find you are trying to print to a window which no longer exists. There is no Close Box, no System Menu, nor is ALT-F4 recognized as a close command. They can only be closed by executing TXT.END, or by terminating the entire application.

TXT METHODS

TXT.CELL

Syntax

```
TXT.CELL = RowValue&, ColValue&
TXT.CELL TO RowVar&, ColVar&
TXT.COL TO ColVar&    <or>    ColVar& = TXT.COL
TXT.ROW TO RowVar&    <or>    RowVar& = TXT.ROW
```

Remarks

TXT.CELL is used to set or retrieve the cursor position, based upon the row and column position of a Text Cell. That is the row and column position where the next printed text will be displayed. *RowValue&* specifies the horizontal screen row (starting at 1) at which to position the cursor. *ColValue&* specifies the vertical screen column (starting at 1) at which to position the cursor. Since row and column numbers start at one (1), the upper left corner of the Text Window is considered to be cell 1,1.

The first form of TXT.CELL moves the cursor to the desired row and column. If a value given is zero (0), that parameter is ignored and that position is not changed. The second form of TXT.CELL retrieves the current cursor position, and assigns the values to the variables specified by *RowVar&* and *ColVar&*.

The last two forms allow you to retrieve just a single value, either row or column, and are supported in both statement and function form.

TXT.CLS

Syntax `TXT.CLS`

Remarks The text window is cleared, and the caret (next print position) is moved to the upper left corner (row 1, column 1).

TXT.COLOR

Syntax `TXT.COLOR = RGBColor&`

Remarks TXT.COLOR is used to change the foreground color of new text drawn with TXT.PRINT. Existing text on the Text Window is not changed. PowerBASIC includes many built-in RGB color equates which may be used here, like %RGB_RED, %RGB_BLUE, etc.

TXT.END

Syntax `TXT.END`

Remarks The Text Window currently attached to your program is destroyed and detached from the process. No errors are generated, even if no Text Window is currently attached.

TXT.INKEY$

Syntax

```
TXT.INKEY$ TO InkeyVar$
InkeyVar$ = TXT.INKEY$
```

Remarks Reads a keyboard character if one is ready. TXT.INKEY$ returns a

of 0 or 1 characters that reflects the status of the keyboard buffer for the current text window. A null string (LEN=0) means that the buffer is empty - no key was pressed.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.INKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.INSTAT

Syntax

```
TXT.INSTAT TO InStatVar&
InstatVar& = TXT.INSTAT
```

Remarks Determines whether a keyboard character is ready. The

variable receives the keyboard buffer status for the current text window. The value assigned is TRUE (non-zero) if a keyboard character is ready to be retrieved, or FALSE (zero) if not.

TXT.INSTAT does not remove the character from the buffer, so repeated execution will continue to return TRUE until the character is read with TXT.INKEY$, TXT.LINE.INPUT, etc.

TXT.LINE.INPUT

Syntax `TXT.LINE.INPUT(["prompt",] StringVar)`

Remarks Reads an entire line from the keyboard into a string variable, ignoring any delimiters which may be embedded. The prompt is an optional string constant or string equate. Upon execution, the prompt is displayed and the program waits for keyboard input. Keystrokes are accepted until the user presses ENTER, at which time the resulting string is stored into the *StringVar*.

The *StringVar* may be a fixed-length, nul-terminated, or a dynamic string. For fixed-length and nul-terminated strings, keyboard input longer than the string is truncated to fit. Dynamic strings receive the complete keyboard input without truncation. *StringVar* may not be a UDT variable, although fixed-length and nul-terminated UDT member variables are allowed.

TXT.PRINT

Syntax `TXT.PRINT([ExprList] [SPC(n)] [TAB(n)] [,] [;]...)`

Remarks Write text data to the TEXT WINDOW at the current caret location. The TXT.PRINT method has the following parts, which may occur in any order and quantity:

ExprList: Numeric and/or string expression(s) to be written to the TEXT WINDOW.

SPC(*n*) An optional function used to insert *n* spaces into the printed output. Multiple use of the SPC argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

TAB(*n*) An optional function used to tab to the *n*th column before printing an expression. Multiple use of the TAB argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

; and , are special characters that determine the position of the next text item printed. A semicolon (;) means the next text item is printed immediately; a comma (,) means the next text item is printed at the start of the next print zone. Print zones begin every 14 columns.

If the final argument of TXT.PRINT is a semicolon or comma, the caret position is maintained at the current location, rather than the default action of moving the print position to the start of the next line. For example:

```
TXT.PRINT "Hello";
TXT.PRINT " world!";
```

...produces the contiguous result "Hello world!"

If you omit all arguments, TXT.PRINT prints a blank line. Printing always begins at the current caret position.

Any control codes, such as Carriage Return, Line-Feed and Backspace are not interpreted. They will display on the screen as symbols.

It is not possible to print a User-Defined Type (UDT), a Variant, an object variable, or an entire array. Individual member values must be extracted with the appropriate function before they can be displayed.

TXT.WAITKEY$

Syntax
```
TXT.WAITKEY$ [TO WaitVar$]
WaitVar$ = TXT.WAITKEY$
```

Remarks Reads a keyboard character, waiting until one is ready. It removes the character from the keyboard buffer for the Text Window, and optionally assigns it to the string variable. If the TO clause is omitted, the keyboard character is discarded.

TXT.WAITKEY$ returns a string of 0 or 1 characters that reflects the status of the keyboard buffer for the Text Window. A null string (LEN=0) means that there was an error, such as the case when no Text Window currently exists.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.WAITKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.WINDOW

Syntax `TXT.WINDOW(Cap$, x, y [,Rows, Cols]) TO hWin`

Remarks A new Text Window is created and attached to your program. The size of the Window is determined by rows and cols, or defaults to 25 rows and 80 columns. Subsequent TXT Methods will act upon this newly created Text Window.

If the Text Window is created successfully, the handle will be assigned to the variable specified by *hWin*. If it fails, the value zero (0) will be assigned instead. If you try to create a Text Window while another still exists, it will fail. In this case, you must first destroy the prior Text Window, as only one may exist at a time.

The parameters *x* and *y* specify the requested location of the window, relative to the upper left corner of the desktop. The parameters are always given in pixels. Rows and columns optionally specify the size of the window, given in the number of characters which will fit within the borders. If not given, the method defaults to 25 vertical rows by 80 horizontal columns.

TXT METHODS

TXT.CELL

Syntax

```
TXT.CELL = RowValue&, ColValue&
TXT.CELL TO RowVar&, ColVar&
TXT.COL TO ColVar&   <or>   ColVar& = TXT.COL
TXT.ROW TO RowVar&   <or>   RowVar& = TXT.ROW
```

Remarks

TXT.CELL is used to set or retrieve the cursor position, based upon the row and column position of a Text Cell. That is the row and column position where the next printed text will be displayed. *RowValue&* specifies the horizontal screen row (starting at 1) at which to position the cursor. *ColValue&* specifies the vertical screen column (starting at 1) at which to position the cursor. Since row and column numbers start at one (1), the upper left corner of the Text Window is considered to be cell 1,1.

The first form of TXT.CELL moves the cursor to the desired row and column. If a value given is zero (0), that parameter is ignored and that position is not changed. The second form of TXT.CELL retrieves the current cursor position, and assigns the values to the variables specified by *RowVar&* and *ColVar&*.

The last two forms allow you to retrieve just a single value, either row or column, and are supported in both statement and function form.

TXT.CLS

Syntax

```
TXT.CLS
```

Remarks

The text window is cleared, and the caret (next print position) is moved to the upper left corner (row 1, column 1).

TXT.COLOR

Syntax

```
TXT.COLOR = RGBColor&
```

Remarks

TXT.COLOR is used to change the foreground color of new text drawn with TXT.PRINT. Existing text on the Text Window is not changed. PowerBASIC includes many built-in RGB color equates which may be used here, like %RGB_RED, %RGB_BLUE, etc.

TXT.END

Syntax

```
TXT.END
```

Remarks The Text Window currently attached to your program is destroyed and detached from the process. No errors are generated, even if no Text Window is currently attached.

TXT.INKEY$

Syntax
```
TXT.INKEY$ TO InkeyVar$
InkeyVar$ = TXT.INKEY$
```

Remarks Reads a keyboard character if one is ready. TXT.INKEY$ returns a

of 0 or 1 characters that reflects the status of the keyboard buffer for the current text window. A null string (LEN=0) means that the buffer is empty - no key was pressed.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.INKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.INSTAT

Syntax
```
TXT.INSTAT TO InStatVar&
InstatVar& = TXT.INSTAT
```

Remarks Determines whether a keyboard character is ready. The

variable receives the keyboard buffer status for the current text window. The value assigned is TRUE (non-zero) if a keyboard character is ready to be retrieved, or FALSE (zero) if not.

TXT.INSTAT does not remove the character from the buffer, so repeated execution will continue to return TRUE until the character is read with TXT.INKEY$, TXT.LINE.INPUT, etc.

TXT.LINE.INPUT

Syntax
```
TXT.LINE.INPUT(["prompt",] StringVar)
```

Remarks Reads an entire line from the keyboard into a string variable, ignoring any delimiters which may be embedded. The prompt is an optional string constant or string equate. Upon execution, the prompt is displayed and the program waits for keyboard input. Keystrokes are accepted until the user presses ENTER, at which time the resulting string is stored into the *StringVar*.

The *StringVar* may be a fixed-length, nul-terminated, or a dynamic string. For fixed-length and nul-terminated strings, keyboard input longer than the string is truncated to fit. Dynamic strings receive the complete keyboard input without truncation. *StringVar* may not be a UDT variable, although fixed-length and nul-terminated UDT member variables are allowed.

TXT.PRINT

Syntax
```
TXT.PRINT([ExprList] [SPC(n)] [TAB(n)] [,] [;]...)
```

Remarks Write text data to the TEXT WINDOW at the current caret location. The TXT.PRINT method has the following parts, which may occur in any order and quantity:

ExprList: Numeric and/or string expression(s) to be written to the TEXT WINDOW.

SPC(*n*) An optional function used to insert *n* spaces into the printed output. Multiple use of the SPC argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

TAB(*n*) An optional function used to tab to the *n*th column before printing an expression. Multiple use of the TAB argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

; and , are special characters that determine the position of the next text item printed. A semicolon (;) means the next text item is printed immediately; a comma (,) means the next text item is printed at the start of the next print zone. Print zones begin every 14 columns.

If the final argument of TXT.PRINT is a semicolon or comma, the caret position is maintained at the current location, rather than the default action of moving the print position to the start of the next line. For example:

```
TXT.PRINT "Hello";
TXT.PRINT " world!";
```

...produces the contiguous result "Hello world!"

If you omit all arguments, TXT.PRINT prints a blank line. Printing always begins at the current caret position.

Any control codes, such as Carriage Return, Line-Feed and Backspace are not interpreted. They will display on the screen as symbols.

It is not possible to print a User-Defined Type (UDT), a Variant, an object variable, or an entire array. Individual member values must be extracted with the appropriate function before they can be displayed.

TXT.WAITKEY$

Syntax

TXT.WAITKEY$ [TO *WaitVar$*]
***WaitVar$* = TXT.WAITKEY$**

Remarks

Reads a keyboard character, waiting until one is ready. It removes the character from the keyboard buffer for the Text Window, and optionally assigns it to the string variable. If the TO clause is omitted, the keyboard character is discarded.

TXT.WAITKEY$ returns a string of 0 or 1 characters that reflects the status of the keyboard buffer for the Text Window. A null string (LEN=0) means that there was an error, such as the case when no Text Window currently exists.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.WAITKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.WINDOW

Syntax

TXT.WINDOW(*Cap$*, *x*, *y* [,*Rows*, *Cols*]) TO *hWin*

Remarks

A new Text Window is created and attached to your program. The size of the Window is determined by rows and cols, or defaults to 25 rows and 80 columns. Subsequent TXT Methods will act upon this newly created Text Window.

If the Text Window is created successfully, the handle will be assigned to the variable specified by *hWin*. If it fails, the value zero (0) will be assigned instead. If you try to create a Text Window while another still exists, it will fail. In this case, you must first destroy the prior Text Window, as only one may exist at a time.

The parameters *x* and *y* specify the requested location of the window, relative to the upper left corner of the desktop. The parameters are always given in pixels. Rows and columns optionally specify the size of the window, given in the number of characters which will fit within the borders. If not given, the method defaults to 25 vertical rows by 80 horizontal columns.

DIALOG NEW, GRAPHIC WINDOW, INPUTBOX$, MSGBOX

TXT.COLOR method

Keyword Template

TXT pseudo-object New!

Purpose Displays and inputs text on a specially created TEXT WINDOW. This is similar to a CONSOLE window, with some advantages. Generally speaking, a Text Window is more attractive. But, just like a Console Window, only fixed-width text may be displayed.

Syntax

```
TXT.membername(params)
RetVal = TXT.membername(params)
TXT.membername(params) TO ReturnVariable
```

Remarks Text Windows offer a specific, but limited capability. They are very easy to implement and use, and they offer an excellent means to produce quick and straightforward programs in text mode.

Text Windows offer an excellent path for the beginning programmer, or for anyone who needs a procedural code model. As the name implies, they display only fixed-width text. Further, only one Text Window may exist at a time. If you need snazzy graphics, more specialized fonts, multiple windows, or a GUI interface, you should look to GRAPHIC WINDOWS and GRAPHIC CONTROLS instead.

Text Window methods are accessed like any other object. The object name TXT is followed by a period separator, and the name of the method or property:

```
TXT.Cell = RowValue&, ColumnVal&
```

Text Window methods which return a value may be used in two forms, a statement with a TO clause, or a function which may be used as a term in an expression:

```
TXT.Row TO RowVar&
RowVar& = TXT.Row
```

The two examples above are functionally identical. The choice is simply a matter of your personal preference. If you use the second form (as a function which returns a value), it can be a term in any expression of any complexity.

Most PowerBASIC functions specify graphic and pixel positions as x,y (the horizontal term first, then the vertical term). However, for compatibility with most current and prior versions of BASIC (PowerBASIC included), the functions which reference text rows and columns name the vertical term first (rows, columns).

Text Windows handle text wrapping and auto-scrolling much like a typical Console Window. When printing exceeds the end of a line, the print position wraps to the first column of the next row. When printing exceeds the last row, the entire page is scrolled to open a new line at the bottom.

In order to use the TXT object successfully, you must use care to first create a Text Window in your program. To do this, you can execute the TXT.WINDOW method.

All Text Windows are stable. They cannot be closed unexpectedly by the user, so there are no surprises when you find you are trying to print to a window which no longer exists. There is no Close Box, no System Menu, nor is ALT-F4 recognized as a close command. They can only be closed by executing TXT.END, or by terminating the entire application.

TXT METHODS

TXT.CELL

Syntax

TXT.CELL = *RowValue&, ColValue&*
TXT.CELL TO *RowVar&, ColVar&*
TXT.COL TO *ColVar&* <or> ***ColVar&* = TXT.COL**
TXT.ROW TO *RowVar&* <or> ***RowVar&* = TXT.ROW**

Remarks

TXT.CELL is used to set or retrieve the cursor position, based upon the row and column position of a Text Cell. That is the row and column position where the next printed text will be displayed. *RowValue&* specifies the horizontal screen row (starting at 1) at which to position the cursor. *ColValue&* specifies the vertical screen column (starting at 1) at which to position the cursor. Since row and column numbers start at one (1), the upper left corner of the Text Window is considered to be cell 1,1.

The first form of TXT.CELL moves the cursor to the desired row and column. If a value given is zero (0), that parameter is ignored and that position is not changed. The second form of TXT.CELL retrieves the current cursor position, and assigns the values to the variables specified by *RowVar&* and *ColVar&*.

The last two forms allow you to retrieve just a single value, either row or column, and are supported in both statement and function form.

TXT.CLS

Syntax

TXT.CLS

Remarks

The text window is cleared, and the caret (next print position) is moved to the upper left corner (row 1, column 1).

TXT.COLOR

Syntax

TXT.COLOR = *RGBColor&*

Remarks

TXT.COLOR is used to change the foreground color of new text drawn with TXT.PRINT. Existing text on the Text Window is not changed. PowerBASIC includes many built-in RGB color equates which may be used here, like %RGB_RED, %RGB_BLUE, etc.

TXT.END

Syntax

TXT.END

Remarks

The Text Window currently attached to your program is destroyed and detached from the process. No errors are generated, even if no Text Window is currently attached.

TXT.INKEY$

Syntax

TXT.INKEY$ TO *InkeyVar$*
***InkeyVar$* = TXT.INKEY$**

Remarks

Reads a keyboard character if one is ready. TXT.INKEY$ returns a

of 0 or 1 characters that reflects the status of the keyboard buffer for the current text window. A null string (LEN=0) means that the buffer is empty - no key was pressed.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.INKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.INSTAT

Syntax

TXT.INSTAT TO *InStatVar&*
***InstatVar&* = TXT.INSTAT**

Remarks

Determines whether a keyboard character is ready. The

variable receives the keyboard buffer status for the current text window. The value assigned is TRUE (non-zero) if a keyboard character is ready to be retrieved, or FALSE (zero) if not.

TXT.INSTAT does not remove the character from the buffer, so repeated execution will continue to return TRUE until the character is read with TXT.INKEY$, TXT.LINE.INPUT, etc.

TXT.LINE.INPUT

Syntax **TXT.LINE.INPUT(["*prompt*",] *StringVar*)**

Remarks Reads an entire line from the keyboard into a string variable, ignoring any delimiters which may be embedded. The prompt is an optional string constant or string equate. Upon execution, the prompt is displayed and the program waits for keyboard input. Keystrokes are accepted until the user presses ENTER, at which time the resulting string is stored into the *StringVar*.

The *StringVar* may be a fixed-length, nul-terminated, or a dynamic string. For fixed-length and nul-terminated strings, keyboard input longer than the string is truncated to fit. Dynamic strings receive the complete keyboard input without truncation. *StringVar* may not be a UDT variable, although fixed-length and nul-terminated UDT member variables are allowed.

TXT.PRINT

Syntax **TXT.PRINT([*ExprList*] [SPC(*n*)] [TAB(*n*)] [,] [;]...)**

Remarks Write text data to the TEXT WINDOW at the current caret location. The TXT.PRINT method has the following parts, which may occur in any order and quantity:

ExprList: Numeric and/or string expression(s) to be written to the TEXT WINDOW.

SPC(*n*) An optional function used to insert *n* spaces into the printed output. Multiple use of the SPC argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

TAB(*n*) An optional function used to tab to the *n*th column before printing an expression. Multiple use of the TAB argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

; and , are special characters that determine the position of the next text item printed. A semicolon (;) means the next text item is printed immediately; a comma (,) means the next text item is printed at the start of the next print zone. Print zones begin every 14 columns.

If the final argument of TXT.PRINT is a semicolon or comma, the caret position is maintained at the current location, rather than the default action of moving the print position to the start of the next line. For example:

```
TXT.PRINT "Hello";
TXT.PRINT " world!";
```

...produces the contiguous result "Hello world!"

If you omit all arguments, TXT.PRINT prints a blank line. Printing always begins at the current caret position.

Any control codes, such as Carriage Return, Line-Feed and Backspace are not interpreted. They will display on the screen as symbols.

It is not possible to print a User-Defined Type (UDT), a Variant, an object variable, or an entire array. Individual member values must be extracted with the appropriate function before they can be displayed.

TXT.WAITKEY$

Syntax **TXT.WAITKEY$ [TO *WaitVar$*]**
***WaitVar$* = TXT.WAITKEY$**

Remarks Reads a keyboard character, waiting until one is ready. It removes the character from the keyboard buffer for the Text Window, and optionally assigns it to the string variable. If the

TO clause is omitted, the keyboard character is discarded.

TXT.WAITKEY$ returns a string of 0 or 1 characters that reflects the status of the keyboard buffer for the Text Window. A null string (LEN=0) means that there was an error, such as the case when no Text Window currently exists.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.WAITKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.WINDOW

Syntax `TXT.WINDOW(Cap$, x, y [,Rows, Cols]) TO hWin`

Remarks A new Text Window is created and attached to your program. The size of the Window is determined by rows and cols, or defaults to 25 rows and 80 columns. Subsequent TXT Methods will act upon this newly created Text Window.

If the Text Window is created successfully, the handle will be assigned to the variable specified by *hWin*. If it fails, the value zero (0) will be assigned instead. If you try to create a Text Window while another still exists, it will fail. In this case, you must first destroy the prior Text Window, as only one may exist at a time.

The parameters *x* and *y* specify the requested location of the window, relative to the upper left corner of the desktop. The parameters are always given in pixels. Rows and columns optionally specify the size of the window, given in the number of characters which will fit within the borders. If not given, the method defaults to 25 vertical rows by 80 horizontal columns.

TXT.END method

Keyword Template

Purpose

Syntax

Remarks

See also

Example

TXT pseudo-object New!

Purpose Displays and inputs text on a specially created TEXT WINDOW. This is similar to a CONSOLE window, with some advantages. Generally speaking, a Text Window is more attractive. But, just like a Console Window, only fixed-width text may be displayed.

Syntax

```
TXT.membername(params)
RetVal = TXT.membername(params)
TXT.membername(params) TO ReturnVariable
```

Remarks Text Windows offer a specific, but limited capability. They are very easy to implement and use, and they offer an excellent means to produce quick and straightforward programs in text mode.

Text Windows offer an excellent path for the beginning programmer, or for anyone who needs a procedural code model. As the name implies, they display only fixed-width text. Further, only one Text Window may exist at a time. If you need snazzy graphics, more specialized fonts, multiple windows, or a GUI interface, you should look to GRAPHIC WINDOWS and GRAPHIC CONTROLS instead.

Text Window methods are accessed like any other object. The object name TXT is followed by a period separator, and the name of the method or property:

```
TXT.Cell = RowValue&, ColumnVal&
```

Text Window methods which return a value may be used in two forms, a statement with a TO clause, or a function which may be used as a term in an expression:

```
TXT.Row TO RowVar&
RowVar& = TXT.Row
```

The two examples above are functionally identical. The choice is simply a matter of your personal preference. If you use the second form (as a function which returns a value), it can be a term in any expression of any complexity.

Most PowerBASIC functions specify graphic and pixel positions as x,y (the horizontal term first, then the vertical term). However, for compatibility with most current and prior versions of BASIC (PowerBASIC included), the functions which reference text rows and columns name the vertical term first (rows, columns).

Text Windows handle text wrapping and auto-scrolling much like a typical Console Window. When printing exceeds the end of a line, the print position wraps to the first column of the next row. When printing exceeds the last row, the entire page is scrolled to open a new line at the bottom.

In order to use the TXT object successfully, you must use care to first create a Text Window in your program. To do this, you can execute the TXT.WINDOW method.

All Text Windows are stable. They cannot be closed unexpectedly by the user, so there are no surprises when you find you are trying to print to a window which no longer exists. There is no Close Box, no System Menu, nor is ALT-F4 recognized as a close command. They can only be closed by executing TXT.END, or by terminating the entire application.

TXT METHODS

TXT.CELL

Syntax

```
TXT.CELL = RowValue&, ColValue&
TXT.CELL TO RowVar&, ColVar&
TXT.COL TO ColVar&    <or>    ColVar& = TXT.COL
TXT.ROW TO RowVar&    <or>    RowVar& = TXT.ROW
```

Remarks

TXT.CELL is used to set or retrieve the cursor position, based upon the row and column position of a Text Cell. That is the row and column position where the next printed text will be displayed. *RowValue&* specifies the horizontal screen row (starting at 1) at which to position the cursor. *ColValue&* specifies the vertical screen column (starting at 1) at which to position the cursor. Since row and column numbers start at one (1), the upper left corner of the Text Window is considered to be cell 1,1.

The first form of TXT.CELL moves the cursor to the desired row and column. If a value given is zero (0), that parameter is ignored and that position is not changed. The second form of TXT.CELL retrieves the current cursor position, and assigns the values to the variables specified by *RowVar&* and *ColVar&*.

The last two forms allow you to retrieve just a single value, either row or column, and are supported in both statement and function form.

TXT.CLS

Syntax

```
TXT.CLS
```

Remarks

The text window is cleared, and the caret (next print position) is moved to the upper left corner (row 1, column 1).

TXT.COLOR

Syntax `TXT.COLOR = RGBColor&`

Remarks TXT.COLOR is used to change the foreground color of new text drawn with TXT.PRINT. Existing text on the Text Window is not changed. PowerBASIC includes many built-in RGB color equates which may be used here, like %RGB_RED, %RGB_BLUE, etc.

TXT.END

Syntax `TXT.END`

Remarks The Text Window currently attached to your program is destroyed and detached from the process. No errors are generated, even if no Text Window is currently attached.

TXT.INKEY$

Syntax

```
TXT.INKEY$ TO InkeyVar$
InkeyVar$ = TXT.INKEY$
```

Remarks Reads a keyboard character if one is ready. TXT.INKEY$ returns a

of 0 or 1 characters that reflects the status of the keyboard buffer for the current text window. A null string (LEN=0) means that the buffer is empty - no key was pressed.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.INKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.INSTAT

Syntax

```
TXT.INSTAT TO InStatVar&
InstatVar& = TXT.INSTAT
```

Remarks Determines whether a keyboard character is ready. The

variable receives the keyboard buffer status for the current text window. The value assigned is TRUE (non-zero) if a keyboard character is ready to be retrieved, or FALSE (zero) if not.

TXT.INSTAT does not remove the character from the buffer, so repeated execution will continue to return TRUE until the character is read with TXT.INKEY$, TXT.LINE.INPUT, etc.

TXT.LINE.INPUT

Syntax `TXT.LINE.INPUT(["prompt",] StringVar)`

Remarks Reads an entire line from the keyboard into a string variable, ignoring any delimiters which may be embedded. The prompt is an optional string constant or string equate. Upon execution, the prompt is displayed and the program waits for keyboard input. Keystrokes are accepted until the user presses ENTER, at which time the resulting string is stored into the *StringVar*.

The *StringVar* may be a fixed-length, nul-terminated, or a dynamic string. For fixed-length and nul-terminated strings, keyboard input longer than the string is truncated to fit. Dynamic strings receive the complete keyboard input without truncation. *StringVar* may not be a UDT variable, although fixed-length and nul-terminated UDT member variables are allowed.

TXT.PRINT

Syntax `TXT.PRINT([ExprList] [SPC(n)] [TAB(n)] [,] [;]...)`

Remarks Write text data to the TEXT WINDOW at the current caret location. The TXT.PRINT method has the following parts, which may occur in any order and quantity:

ExprList: Numeric and/or string expression(s) to be written to the TEXT WINDOW.

SPC(*n*) An optional function used to insert *n* spaces into the printed output. Multiple use of the SPC argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

TAB(*n*) An optional function used to tab to the *n*th column before printing an expression. Multiple use of the TAB argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

; and , are special characters that determine the position of the next text item printed. A semicolon (;) means the next text item is printed immediately; a comma (,) means the next text item is printed at the start of the next print zone. Print zones begin every 14 columns.

If the final argument of TXT.PRINT is a semicolon or comma, the caret position is maintained at the current location, rather than the default action of moving the print position to the start of the next line. For example:

```
TXT.PRINT "Hello";
TXT.PRINT " world!";
```

...produces the contiguous result "Hello world!"

If you omit all arguments, TXT.PRINT prints a blank line. Printing always begins at the current caret position.

Any control codes, such as Carriage Return, Line-Feed and Backspace are not interpreted. They will display on the screen as symbols.

It is not possible to print a User-Defined Type (UDT), a Variant, an object variable, or an entire array. Individual member values must be extracted with the appropriate function before they can be displayed.

TXT.WAITKEY$

Syntax

```
TXT.WAITKEY$ [TO WaitVar$]
WaitVar$ = TXT.WAITKEY$
```

Remarks

Reads a keyboard character, waiting until one is ready. It removes the character from the keyboard buffer for the Text Window, and optionally assigns it to the string variable. If the TO clause is omitted, the keyboard character is discarded.

TXT.WAITKEY$ returns a string of 0 or 1 characters that reflects the status of the keyboard buffer for the Text Window. A null string (LEN=0) means that there was an error, such as the case when no Text Window currently exists.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.WAITKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.WINDOW

Syntax

```
TXT.WINDOW(Cap$, x, y [,Rows, Cols]) TO hWin
```

Remarks

A new Text Window is created and attached to your program. The size of the Window is determined by rows and cols, or defaults to 25 rows and 80 columns. Subsequent TXT Methods will act upon this newly created Text Window.

If the Text Window is created successfully, the handle will be assigned to the variable specified by *hWin*. If it fails, the value zero (0) will be assigned instead. If you try to create a Text Window while another still exists, it will fail. In this case, you must first destroy the prior Text Window, as only one may exist at a time.

The parameters *x* and *y* specify the requested location of the window, relative to the upper left corner of the desktop. The parameters are always given in pixels. Rows and columns optionally specify the size of the window, given in the number of characters which will fit within the borders. If not given, the method defaults to 25 vertical rows by 80 horizontal columns.

The first form of TXT.CELL moves the cursor to the desired row and column. If a value given is zero (0), that parameter is ignored and that position is not changed. The second form of TXT.CELL retrieves the current cursor position, and assigns the values to the variables specified by *RowVar&* and *ColVar&*.

The last two forms allow you to retrieve just a single value, either row or column, and are supported in both statement and function form.

TXT.CLS

Syntax

```
TXT.CLS
```

Remarks

The text window is cleared, and the caret (next print position) is moved to the upper left corner (row 1, column 1).

TXT.COLOR

Syntax

```
TXT.COLOR = RGBColor&
```

Remarks

TXT.COLOR is used to change the foreground color of new text drawn with TXT.PRINT. Existing text on the Text Window is not changed. PowerBASIC includes many built-in RGB color equates which may be used here, like %RGB_RED, %RGB_BLUE, etc.

TXT.END

Syntax

```
TXT.END
```

Remarks

The Text Window currently attached to your program is destroyed and detached from the process. No errors are generated, even if no Text Window is currently attached.

TXT.INKEY$

Syntax

```
TXT.INKEY$ TO InkeyVar$
InkeyVar$ = TXT.INKEY$
```

Remarks

Reads a keyboard character if one is ready. TXT.INKEY$ returns a

of 0 or 1 characters that reflects the status of the keyboard buffer for the current text window. A null string (LEN=0) means that the buffer is empty - no key was pressed.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.INKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.INSTAT

Syntax

```
TXT.INSTAT TO InStatVar&
InstatVar& = TXT.INSTAT
```

Remarks

Determines whether a keyboard character is ready. The variable receives the keyboard buffer status for the current text window. The value assigned is TRUE (non-zero) if a keyboard character is ready to be retrieved, or FALSE (zero) if not.

TXT.INSTAT does not remove the character from the buffer, so repeated execution will continue to return TRUE until the character is read with TXT.INKEY$, TXT.LINE.INPUT, etc.

TXT.LINE.INPUT

Syntax

```
TXT.LINE.INPUT(["prompt",] StringVar)
```

Remarks

Reads an entire line from the keyboard into a string variable, ignoring any delimiters which may be embedded. The prompt is an optional string constant or string equate. Upon execution, the prompt is displayed and the program waits for keyboard input. Keystrokes are accepted until the user presses ENTER, at which time the resulting string is stored into the *StringVar*.

The *StringVar* may be a fixed-length, nul-terminated, or a dynamic string. For fixed-length and nul-terminated strings, keyboard input longer than the string is truncated to fit. Dynamic strings receive the complete keyboard input without truncation. *StringVar* may not be a UDT variable, although fixed-length and nul-terminated UDT member variables are allowed.

TXT.PRINT

Syntax

```
TXT.PRINT([ExprList] [SPC(n)] [TAB(n)] [,] [;]...)
```

Remarks

Write text data to the TEXT WINDOW at the current caret location. The TXT.PRINT method has the following parts, which may occur in any order and quantity:

ExprList: Numeric and/or string expression(s) to be written to the TEXT WINDOW.

SPC(*n*)	An optional function used to insert *n* spaces into the printed output. Multiple use of the SPC argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.
TAB(*n*)	An optional function used to tab to the *n*th column before printing an expression. Multiple use of the TAB argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

; and , are special characters that determine the position of the next text item printed. A semicolon (;) means the next text item is printed immediately; a comma (,) means the next text item is printed at the start of the next print zone. Print zones begin every 14 columns.

If the final argument of TXT.PRINT is a semicolon or comma, the caret position is maintained at the current location, rather than the default action of moving the print position to the start of the next line. For example:

```
TXT.PRINT "Hello";
TXT.PRINT " world!";
```

...produces the contiguous result "Hello world!"

If you omit all arguments, TXT.PRINT prints a blank line. Printing always begins at the current caret position.

Any control codes, such as Carriage Return, Line-Feed and Backspace are not interpreted. They will display on the screen as symbols.

It is not possible to print a User-Defined Type (UDT), a Variant, an object variable, or an entire array. Individual member values must be extracted with the appropriate function before they can be displayed.

TXT.WAITKEY$

Syntax

```
TXT.WAITKEY$ [TO WaitVar$]
WaitVar$ = TXT.WAITKEY$
```

Remarks

Reads a keyboard character, waiting until one is ready. It removes the character from the keyboard buffer for the Text Window, and optionally assigns it to the string variable. If the TO clause is omitted, the keyboard character is discarded.

TXT.WAITKEY$ returns a string of 0 or 1 characters that reflects the status of the keyboard buffer for the Text Window. A null string (LEN=0) means that there was an error, such as the case when no Text Window currently exists.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.WAITKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.WINDOW

Syntax

```
TXT.WINDOW(Cap$, x, y [,Rows, Cols]) TO hWin
```

Remarks

A new Text Window is created and attached to your program. The size of the Window is determined by rows and cols, or defaults to 25 rows and 80 columns. Subsequent TXT Methods will act upon this newly created Text Window.

If the Text Window is created successfully, the handle will be assigned to the variable specified by *hWin*. If it fails, the value zero (0) will be assigned instead. If you try to create a Text Window while another still exists, it will fail. In this case, you must first destroy the prior Text Window, as only one may exist at a time.

The parameters *x* and *y* specify the requested location of the window, relative to the upper left corner of the desktop. The parameters are always given in pixels. Rows and columns optionally specify the size of the window, given in the number of characters which will fit within the borders. If not given, the method defaults to 25 vertical rows by 80 horizontal columns.

All Text Windows are stable. They cannot be closed unexpectedly by the user, so there are no surprises when you find you are trying to print to a window which no longer exists. There is no Close Box, no System Menu, nor is ALT-F4 recognized as a close command. They can only be closed by executing TXT.END, or by terminating the entire application.

TXT METHODS

TXT.CELL

Syntax

```
TXT.CELL = RowValue&, ColValue&
TXT.CELL TO RowVar&, ColVar&
TXT.COL TO ColVar&    <or>    ColVar& = TXT.COL
TXT.ROW TO RowVar&    <or>    RowVar& = TXT.ROW
```

Remarks

TXT.CELL is used to set or retrieve the cursor position, based upon the row and column position of a Text Cell. That is the row and column position where the next printed text will be displayed. *RowValue&* specifies the horizontal screen row (starting at 1) at which to position the cursor. *ColValue&* specifies the vertical screen column (starting at 1) at which to position the cursor. Since row and column numbers start at one (1), the upper left corner of the Text Window is considered to be cell 1,1.

The first form of TXT.CELL moves the cursor to the desired row and column. If a value given is zero (0), that parameter is ignored and that position is not changed. The second form of TXT.CELL retrieves the current cursor position, and assigns the values to the variables specified by *RowVar&* and *ColVar&*.

The last two forms allow you to retrieve just a single value, either row or column, and are supported in both statement and function form.

TXT.CLS

Syntax `TXT.CLS`

Remarks The text window is cleared, and the caret (next print position) is moved to the upper left corner (row 1, column 1).

TXT.COLOR

Syntax `TXT.COLOR = RGBColor&`

Remarks TXT.COLOR is used to change the foreground color of new text drawn with TXT.PRINT. Existing text on the Text Window is not changed. PowerBASIC includes many built-in RGB color equates which may be used here, like %RGB_RED, %RGB_BLUE, etc.

TXT.END

Syntax `TXT.END`

Remarks The Text Window currently attached to your program is destroyed and detached from the process. No errors are generated, even if no Text Window is currently attached.

TXT.INKEY$

Syntax

```
TXT.INKEY$ TO InkeyVar$
InkeyVar$ = TXT.INKEY$
```

Remarks Reads a keyboard character if one is ready. TXT.INKEY$ returns a

of 0 or 1 characters that reflects the status of the keyboard buffer for the current text window. A null string (LEN=0) means that the buffer is empty - no key was pressed.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.INKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.INSTAT

Syntax

```
TXT.INSTAT TO InStatVar&
InstatVar& = TXT.INSTAT
```

Remarks Determines whether a keyboard character is ready. The

variable receives the keyboard buffer status for the current text window. The value assigned is TRUE (non-zero) if a keyboard character is ready to be retrieved, or FALSE (zero) if not.

TXT.INSTAT does not remove the character from the buffer, so repeated execution will continue to return TRUE until the character is read with TXT.INKEY$, TXT.LINE.INPUT, etc.

TXT.LINE.INPUT

Syntax `TXT.LINE.INPUT(["prompt",] StringVar)`

Remarks Reads an entire line from the keyboard into a string variable, ignoring any delimiters which may be embedded. The prompt is an optional string constant or string equate. Upon execution, the prompt is displayed and the program waits for keyboard input. Keystrokes are accepted until the user presses ENTER, at which time the resulting string is stored into the *StringVar*.

The *StringVar* may be a fixed-length, nul-terminated, or a dynamic string. For fixed-length and nul-terminated strings, keyboard input longer than the string is truncated to fit. Dynamic strings receive the complete keyboard input without truncation. *StringVar* may not be a UDT variable, although fixed-length and nul-terminated UDT member variables are allowed.

TXT.PRINT

Syntax `TXT.PRINT([ExprList] [SPC(n)] [TAB(n)] [,] [;]...)`

Remarks Write text data to the TEXT WINDOW at the current caret location. The TXT.PRINT method has the following parts, which may occur in any order and quantity:

ExprList: Numeric and/or string expression(s) to be written to the TEXT WINDOW.

SPC(*n*) An optional function used to insert *n* spaces into the printed output. Multiple use of the SPC argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

TAB(*n*) An optional function used to tab to the *n*th column before printing an expression. Multiple use of the TAB argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

; and , are special characters that determine the position of the next text item printed. A semicolon (;) means the next text item is printed immediately; a comma (,) means the next text item is printed at the start of the next print zone. Print zones begin every 14 columns.

If the final argument of TXT.PRINT is a semicolon or comma, the caret position is maintained at the current location, rather than the default action of moving the print position to the start of the next line. For example:

```
TXT.PRINT "Hello";
TXT.PRINT " world!";
```

...produces the contiguous result "Hello world!"

If you omit all arguments, TXT.PRINT prints a blank line. Printing always begins at the current caret position.

Any control codes, such as Carriage Return, Line-Feed and Backspace are not interpreted. They will display on the screen as symbols.

It is not possible to print a User-Defined Type (UDT), a Variant, an object variable, or an entire array. Individual member values must be extracted with the appropriate function before they can be displayed.

TXT.WAITKEY$

Syntax `TXT.WAITKEY$ [TO WaitVar$]`
`WaitVar$ = TXT.WAITKEY$`

Remarks Reads a keyboard character, waiting until one is ready. It removes the character from the keyboard buffer for the Text Window, and optionally assigns it to the string variable. If the TO clause is omitted, the keyboard character is discarded.

TXT.WAITKEY$ returns a string of 0 or 1 characters that reflects the status of the keyboard buffer for the Text Window. A null string (LEN=0) means that there was an error, such as the case when no Text Window currently exists.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.WAITKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.WINDOW

Syntax `TXT.WINDOW(Cap$, x, y [,Rows, Cols]) TO hWin`

Remarks A new Text Window is created and attached to your program. The size of the Window is determined by rows and cols, or defaults to 25 rows and 80 columns. Subsequent TXT Methods will act upon this newly created Text Window.

If the Text Window is created successfully, the handle will be assigned to the variable specified by *hWin*. If it fails, the value zero (0) will be assigned instead. If you try to create a Text Window while another still exists, it will fail. In this case, you must first destroy the prior Text Window, as only one may exist at a time.

The parameters *x* and *y* specify the requested location of the window, relative to the upper left corner of the desktop. The parameters are always given in pixels. Rows and columns optionally specify the size of the window, given in the number of characters which will fit within the borders. If not given, the method defaults to 25 vertical rows by 80 horizontal columns.

TXT.LINE.INPUT method

Keyword Template

Purpose

Syntax

Remarks

See also

Example

TXT pseudo-object New!

Purpose Displays and inputs text on a specially created TEXT WINDOW. This is similar to a CONSOLE window, with some advantages. Generally speaking, a Text Window is more attractive. But, just like a Console Window, only fixed-width text may be displayed.

Syntax

```
TXT.membername(params)
RetVal = TXT.membername(params)
TXT.membername(params) TO ReturnVariable
```

Remarks Text Windows offer a specific, but limited capability. They are very easy to implement and use, and they offer an excellent means to produce quick and straightforward programs in text mode.

Text Windows offer an excellent path for the beginning programmer, or for anyone who needs a procedural code model. As the name implies, they display only fixed-width text. Further, only one Text Window may exist at a time. If you need snazzy graphics, more specialized fonts, multiple windows, or a GUI interface, you should look to GRAPHIC WINDOWS and GRAPHIC CONTROLS instead.

Text Window methods are accessed like any other object. The object name TXT is followed by a period separator, and the name of the method or property:

```
TXT.Cell = RowValue&, ColumnVal&
```

Text Window methods which return a value may be used in two forms, a statement with a TO clause, or a function which may be used as a term in an expression:

```
TXT.Row TO RowVar&
RowVar& = TXT.Row
```

The two examples above are functionally identical. The choice is simply a matter of your personal preference. If you use the second form (as a function which returns a value), it can be a term in any expression of any complexity.

Most PowerBASIC functions specify graphic and pixel positions as x,y (the horizontal term first, then the vertical term). However, for compatibility with most current and prior versions of BASIC (PowerBASIC included), the functions which reference text rows and columns name the vertical term first (rows, columns).

Text Windows handle text wrapping and auto-scrolling much like a typical Console Window. When printing exceeds the end of a line, the print position wraps to the first column of the next row. When printing exceeds the last row, the entire page is scrolled to open a new line at the bottom.

In order to use the TXT object successfully, you must use care to first create a Text Window in your program. To do this, you can execute the TXT.WINDOW method.

All Text Windows are stable. They cannot be closed unexpectedly by the user, so there are no surprises when you find you are trying to print to a window which no longer exists. There is no Close Box, no System Menu, nor is ALT-F4 recognized as a close command. They can only be closed by executing TXT.END, or by terminating the entire application.

TXT METHODS

TXT.CELL

Syntax

```
TXT.CELL = RowValue&, ColValue&
TXT.CELL TO RowVar&, ColVar&
TXT.COL TO ColVar&   <or>   ColVar& = TXT.COL
TXT.ROW TO RowVar&   <or>   RowVar& = TXT.ROW
```

Remarks

TXT.CELL is used to set or retrieve the cursor position, based upon the row and column position of a Text Cell. That is the row and column position where the next printed text will be displayed. *RowValue&* specifies the horizontal screen row (starting at 1) at which to position the cursor. *ColValue&* specifies the vertical screen column (starting at 1) at which to position the cursor. Since row and column numbers start at one (1), the upper left corner of the Text Window is considered to be cell 1,1.

The first form of TXT.CELL moves the cursor to the desired row and column. If a value given is zero (0), that parameter is ignored and that position is not changed. The second form of TXT.CELL retrieves the current cursor position, and assigns the values to the variables specified by *RowVar&* and *ColVar&*.

The last two forms allow you to retrieve just a single value, either row or column, and are supported in both statement and function form.

TXT.CLS

Syntax

```
TXT.CLS
```

Remarks

The text window is cleared, and the caret (next print position) is moved to the upper left corner (row 1, column 1).

TXT.COLOR

Syntax

```
TXT.COLOR = RGBColor&
```

Remarks

TXT.COLOR is used to change the foreground color of new text drawn with TXT.PRINT. Existing text on the Text Window is not changed. PowerBASIC includes many built-in RGB color equates which may be used here, like %RGB_RED, %RGB_BLUE, etc.

TXT.END

Syntax

```
TXT.END
```

Remarks

The Text Window currently attached to your program is destroyed and detached from the process. No errors are generated, even if no Text Window is currently attached.

TXT.INKEY$

Syntax `TXT.INKEY$ TO InkeyVar$`
`InkeyVar$ = TXT.INKEY$`

Remarks Reads a keyboard character if one is ready. TXT.INKEY$ returns a

of 0 or 1 characters that reflects the status of the keyboard buffer for the current text window. A null string (LEN=0) means that the buffer is empty - no key was pressed.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.INKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.INSTAT

Syntax `TXT.INSTAT TO InStatVar&`
`InstatVar& = TXT.INSTAT`

Remarks Determines whether a keyboard character is ready. The

variable receives the keyboard buffer status for the current text window. The value assigned is TRUE (non-zero) if a keyboard character is ready to be retrieved, or FALSE (zero) if not.

TXT.INSTAT does not remove the character from the buffer, so repeated execution will continue to return TRUE until the character is read with TXT.INKEY$, TXT.LINE.INPUT, etc.

TXT.LINE.INPUT

Syntax `TXT.LINE.INPUT(["prompt",] StringVar)`

Remarks Reads an entire line from the keyboard into a string variable, ignoring any delimiters which may be embedded. The prompt is an optional string constant or string equate. Upon execution, the prompt is displayed and the program waits for keyboard input. Keystrokes are accepted until the user presses ENTER, at which time the resulting string is stored into the *StringVar*.

The *StringVar* may be a fixed-length, nul-terminated, or a dynamic string. For fixed-length and nul-terminated strings, keyboard input longer than the string is truncated to fit. Dynamic strings receive the complete keyboard input without truncation. *StringVar* may not be a UDT variable, although fixed-length and nul-terminated UDT member variables are allowed.

TXT.PRINT

Syntax `TXT.PRINT([ExprList] [SPC(n)] [TAB(n)] [,] [;]...)`

Remarks Write text data to the TEXT WINDOW at the current caret location. The TXT.PRINT method has the following parts, which may occur in any order and quantity:

ExprList: Numeric and/or string expression(s) to be written to the TEXT WINDOW.

SPC(*n*) An optional function used to insert *n* spaces into the printed output. Multiple use of the SPC argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

TAB(*n*) An optional function used to tab to the *n*th column before printing an expression. Multiple use of the TAB argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

; and , are special characters that determine the position of the next text item printed. A semicolon (;) means the next text item is printed immediately; a comma (,) means the next text item is printed at the start of the next print zone. Print zones begin every 14 columns.

If the final argument of TXT.PRINT is a semicolon or comma, the caret position is maintained at the current location, rather than the default action of moving the print position to the start of the next line. For example:

```
TXT.PRINT "Hello";
TXT.PRINT " world!";
```

...produces the contiguous result "Hello world!"

If you omit all arguments, TXT.PRINT prints a blank line. Printing always begins at the current caret position.

Any control codes, such as Carriage Return, Line-Feed and Backspace are not interpreted. They will display on the screen as symbols.

It is not possible to print a User-Defined Type (UDT), a Variant, an object variable, or an entire array. Individual member values must be extracted with the appropriate function before they can be displayed.

TXT.WAITKEY$

Syntax

TXT.WAITKEY$ [TO *WaitVar$*]
***WaitVar$* = TXT.WAITKEY$**

Remarks

Reads a keyboard character, waiting until one is ready. It removes the character from the keyboard buffer for the Text Window, and optionally assigns it to the string variable. If the TO clause is omitted, the keyboard character is discarded.

TXT.WAITKEY$ returns a string of 0 or 1 characters that reflects the status of the keyboard buffer for the Text Window. A null string (LEN=0) means that there was an error, such as the case when no Text Window currently exists.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.WAITKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.WINDOW

Syntax

TXT.WINDOW(*Cap$*, *x*, *y* [,*Rows*, *Cols*]) TO *hWin*

Remarks

A new Text Window is created and attached to your program. The size of the Window is determined by rows and cols, or defaults to 25 rows and 80 columns. Subsequent TXT Methods will act upon this newly created Text Window.

If the Text Window is created successfully, the handle will be assigned to the variable specified by *hWin*. If it fails, the value zero (0) will be assigned instead. If you try to create a Text Window while another still exists, it will fail. In this case, you must first destroy the prior Text Window, as only one may exist at a time.

The parameters *x* and *y* specify the requested location of the window, relative to the upper left corner of the desktop. The parameters are always given in pixels. Rows and columns optionally specify the size of the window, given in the number of characters which will fit within the borders. If not given, the method defaults to 25 vertical rows by 80 horizontal columns.

There is no Close Box, no System Menu, nor is ALT-F4 recognized as a close command. They can only be closed by executing TXT.END, or by terminating the entire application.

TXT METHODS

TXT.CELL

Syntax

```
TXT.CELL = RowValue&, ColValue&
TXT.CELL TO RowVar&, ColVar&
TXT.COL TO ColVar&   <or>   ColVar& = TXT.COL
TXT.ROW TO RowVar&   <or>   RowVar& = TXT.ROW
```

Remarks

TXT.CELL is used to set or retrieve the cursor position, based upon the row and column position of a Text Cell. That is the row and column position where the next printed text will be displayed. *RowValue&* specifies the horizontal screen row (starting at 1) at which to position the cursor. *ColValue&* specifies the vertical screen column (starting at 1) at which to position the cursor. Since row and column numbers start at one (1), the upper left corner of the Text Window is considered to be cell 1,1.

The first form of TXT.CELL moves the cursor to the desired row and column. If a value given is zero (0), that parameter is ignored and that position is not changed. The second form of TXT.CELL retrieves the current cursor position, and assigns the values to the variables specified by *RowVar&* and *ColVar&*.

The last two forms allow you to retrieve just a single value, either row or column, and are supported in both statement and function form.

TXT.CLS

Syntax `TXT.CLS`

Remarks The text window is cleared, and the caret (next print position) is moved to the upper left corner (row 1, column 1).

TXT.COLOR

Syntax `TXT.COLOR = RGBColor&`

Remarks TXT.COLOR is used to change the foreground color of new text drawn with TXT.PRINT. Existing text on the Text Window is not changed. PowerBASIC includes many built-in RGB color equates which may be used here, like %RGB_RED, %RGB_BLUE, etc.

TXT.END

Syntax `TXT.END`

Remarks The Text Window currently attached to your program is destroyed and detached from the process. No errors are generated, even if no Text Window is currently attached.

TXT.INKEY$

Syntax

```
TXT.INKEY$ TO InkeyVar$
InkeyVar$ = TXT.INKEY$
```

Remarks Reads a keyboard character if one is ready. TXT.INKEY$ returns a

of 0 or 1 characters that reflects the status of the keyboard buffer for the current text window. A null string (LEN=0) means that the buffer is empty - no key was pressed.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.INKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.INSTAT

Syntax

```
TXT.INSTAT TO InStatVar&
InstatVar& = TXT.INSTAT
```

Remarks Determines whether a keyboard character is ready. The

variable receives the keyboard buffer status for the current text window. The value assigned is TRUE (non-zero) if a keyboard character is ready to be retrieved, or FALSE (zero) if not.

TXT.INSTAT does not remove the character from the buffer, so repeated execution will continue to return TRUE until the character is read with TXT.INKEY$, TXT.LINE.INPUT, etc.

TXT.LINE.INPUT

Syntax `TXT.LINE.INPUT(["prompt",] StringVar)`

Remarks Reads an entire line from the keyboard into a string variable, ignoring any delimiters which may be embedded. The prompt is an optional string constant or string equate. Upon execution, the prompt is displayed and the program waits for keyboard input. Keystrokes are accepted until the user presses ENTER, at which time the resulting string is stored into the *StringVar*.

The *StringVar* may be a fixed-length, nul-terminated, or a dynamic string. For fixed-length and nul-terminated strings, keyboard input longer than the string is truncated to fit. Dynamic strings receive the complete keyboard input without truncation. *StringVar* may not be a UDT variable, although fixed-length and nul-terminated UDT member variables are allowed.

TXT.PRINT

Syntax `TXT.PRINT([ExprList] [SPC(n)] [TAB(n)] [,] [;]...)`

Remarks Write text data to the TEXT WINDOW at the current caret location. The TXT.PRINT method has the following parts, which may occur in any order and quantity:

ExprList: Numeric and/or string expression(s) to be written to the TEXT WINDOW.

SPC(*n*) An optional function used to insert *n* spaces into the printed output. Multiple use of the SPC argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

TAB(*n*) An optional function used to tab to the *n*th column before printing an expression. Multiple use of the TAB argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

; and , are special characters that determine the position of the next text item printed. A semicolon (;) means the next text item is printed immediately; a comma (,) means the next text item is printed at the start of the next print zone. Print zones begin every 14 columns.

If the final argument of TXT.PRINT is a semicolon or comma, the caret position is maintained at the current location, rather than the default action of moving the print position to the start of the next line. For example:

```
TXT.PRINT "Hello";
TXT.PRINT " world!";
```

...produces the contiguous result "Hello world!"

If you omit all arguments, TXT.PRINT prints a blank line. Printing always begins at the current caret position.

Any control codes, such as Carriage Return, Line-Feed and Backspace are not interpreted. They will display on the screen as symbols.

It is not possible to print a User-Defined Type (UDT), a Variant, an object variable, or an entire array. Individual member values must be extracted with the appropriate function before they can be displayed.

TXT.WAITKEY$

Syntax
```
TXT.WAITKEY$ [TO WaitVar$]
WaitVar$ = TXT.WAITKEY$
```

Remarks Reads a keyboard character, waiting until one is ready. It removes the character from the keyboard buffer for the Text Window, and optionally assigns it to the string variable. If the TO clause is omitted, the keyboard character is discarded.

TXT.WAITKEY$ returns a string of 0 or 1 characters that reflects the status of the keyboard buffer for the Text Window. A null string (LEN=0) means that there was an error, such as the case when no Text Window currently exists.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.WAITKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.WINDOW

Syntax `TXT.WINDOW(Cap$, x, y [,Rows, Cols]) TO hWin`

Remarks A new Text Window is created and attached to your program. The size of the Window is determined by rows and cols, or defaults to 25 rows and 80 columns. Subsequent TXT Methods will act upon this newly created Text Window.

If the Text Window is created successfully, the handle will be assigned to the variable specified by *hWin*. If it fails, the value zero (0) will be assigned instead. If you try to create a Text Window while another still exists, it will fail. In this case, you must first destroy the prior Text Window, as only one may exist at a time.

The parameters *x* and *y* specify the requested location of the window, relative to the upper left corner of the desktop. The parameters are always given in pixels. Rows and columns optionally specify the size of the window, given in the number of characters which will fit within the borders. If not given, the method defaults to 25 vertical rows by 80 horizontal columns.

TXT METHODS

TXT.CELL

Syntax

```
TXT.CELL = RowValue&, ColValue&
TXT.CELL TO RowVar&, ColVar&
TXT.COL TO ColVar&    <or>    ColVar& = TXT.COL
TXT.ROW TO RowVar&    <or>    RowVar& = TXT.ROW
```

Remarks

TXT.CELL is used to set or retrieve the cursor position, based upon the row and column position of a Text Cell. That is the row and column position where the next printed text will be displayed. *RowValue&* specifies the horizontal screen row (starting at 1) at which to position the cursor. *ColValue&* specifies the vertical screen column (starting at 1) at which to position the cursor. Since row and column numbers start at one (1), the upper left corner of the Text Window is considered to be cell 1,1.

The first form of TXT.CELL moves the cursor to the desired row and column. If a value given is zero (0), that parameter is ignored and that position is not changed. The second form of TXT.CELL retrieves the current cursor position, and assigns the values to the variables specified by *RowVar&* and *ColVar&*.

The last two forms allow you to retrieve just a single value, either row or column, and are supported in both statement and function form.

TXT.CLS

Syntax

```
TXT.CLS
```

Remarks

The text window is cleared, and the caret (next print position) is moved to the upper left corner (row 1, column 1).

TXT.COLOR

Syntax

```
TXT.COLOR = RGBColor&
```

Remarks

TXT.COLOR is used to change the foreground color of new text drawn with TXT.PRINT. Existing text on the Text Window is not changed. PowerBASIC includes many built-in RGB color equates which may be used here, like %RGB_RED, %RGB_BLUE, etc.

TXT.END

Syntax `TXT.END`

Remarks The Text Window currently attached to your program is destroyed and detached from the process. No errors are generated, even if no Text Window is currently attached.

TXT.INKEY$

Syntax

```
TXT.INKEY$ TO InkeyVar$
InkeyVar$ = TXT.INKEY$
```

Remarks Reads a keyboard character if one is ready. TXT.INKEY$ returns a

of 0 or 1 characters that reflects the status of the keyboard buffer for the current text window. A null string (LEN=0) means that the buffer is empty - no key was pressed.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.INKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.INSTAT

Syntax

```
TXT.INSTAT TO InStatVar&
InstatVar& = TXT.INSTAT
```

Remarks Determines whether a keyboard character is ready. The

variable receives the keyboard buffer status for the current text window. The value assigned is TRUE (non-zero) if a keyboard character is ready to be retrieved, or FALSE (zero) if not.

TXT.INSTAT does not remove the character from the buffer, so repeated execution will continue to return TRUE until the character is read with TXT.INKEY$, TXT.LINE.INPUT, etc.

TXT.LINE.INPUT

Syntax

```
TXT.LINE.INPUT(["prompt",] StringVar)
```

Remarks Reads an entire line from the keyboard into a string variable, ignoring any delimiters which may be embedded. The prompt is an optional string constant or string equate. Upon execution, the prompt is displayed and the program waits for keyboard input. Keystrokes are accepted until the user presses ENTER, at which time the resulting string is stored into the *StringVar*.

The *StringVar* may be a fixed-length, nul-terminated, or a dynamic string. For fixed-length and nul-terminated strings, keyboard input longer than the string is truncated to fit. Dynamic strings receive the complete keyboard input without truncation. *StringVar* may not be a UDT variable, although fixed-length and nul-terminated UDT member variables are allowed.

TXT.PRINT

Syntax

```
TXT.PRINT([ExprList] [SPC(n)] [TAB(n)] [,] [;]...)
```

Remarks Write text data to the TEXT WINDOW at the current caret location. The TXT.PRINT method has the following parts, which may occur in any order and quantity:

ExprList: Numeric and/or string expression(s) to be written to the TEXT WINDOW.

SPC(*n*) An optional function used to insert *n* spaces into the printed output. Multiple use of the SPC argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

TAB(*n*) An optional function used to tab to the *n*th column before printing an expression. Multiple use of the TAB argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

; and , are special characters that determine the position of the next text item printed. A semicolon (;) means the next text item is printed immediately; a comma (,) means the next text item is printed at the start of the next print zone. Print zones begin every 14 columns.

If the final argument of TXT.PRINT is a semicolon or comma, the caret position is maintained at the current location, rather than the default action of moving the print position to the start of the next line. For example:

```
TXT.PRINT "Hello";
TXT.PRINT " world!";
```

...produces the contiguous result "Hello world!"

If you omit all arguments, TXT.PRINT prints a blank line. Printing always begins at the current caret position.

Any control codes, such as Carriage Return, Line-Feed and Backspace are not interpreted. They will display on the screen as symbols.

It is not possible to print a User-Defined Type (UDT), a Variant, an object variable, or an entire array. Individual member values must be extracted with the appropriate function before they can be displayed.

TXT.WAITKEY$

Syntax

```
TXT.WAITKEY$ [TO WaitVar$]
WaitVar$ = TXT.WAITKEY$
```

Remarks

Reads a keyboard character, waiting until one is ready. It removes the character from the keyboard buffer for the Text Window, and optionally assigns it to the string variable. If the TO clause is omitted, the keyboard character is discarded.

TXT.WAITKEY$ returns a string of 0 or 1 characters that reflects the status of the keyboard buffer for the Text Window. A null string (LEN=0) means that there was an error, such as the case when no Text Window currently exists.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.WAITKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.WINDOW

Syntax

```
TXT.WINDOW(Cap$, x, y [,Rows, Cols]) TO hWin
```

Remarks

A new Text Window is created and attached to your program. The size of the Window is determined by rows and cols, or defaults to 25 rows and 80 columns. Subsequent TXT Methods will act upon this newly created Text Window.

If the Text Window is created successfully, the handle will be assigned to the variable specified by *hWin*. If it fails, the value zero (0) will be assigned instead. If you try to create a Text Window while another still exists, it will fail. In this case, you must first destroy the prior Text Window, as only one may exist at a time.

The parameters *x* and *y* specify the requested location of the window, relative to the upper left corner of the desktop. The parameters are always given in pixels. Rows and columns optionally specify the size of the window, given in the number of characters which will fit within the borders. If not given, the method defaults to 25 vertical rows by 80 horizontal columns.

TXT.WINDOW method

Keyword Template

Purpose

Syntax

Remarks

See also

Example

TXT pseudo-object New!

Purpose

Displays and inputs text on a specially created TEXT WINDOW. This is similar to a CONSOLE window, with some advantages. Generally speaking, a Text Window is more attractive. But, just like a Console Window, only fixed-width text may be displayed.

Syntax

```
TXT.membername(params)
RetVal = TXT.membername(params)
TXT.membername(params) TO ReturnVariable
```

Remarks

Text Windows offer a specific, but limited capability. They are very easy to implement and use, and they offer an excellent means to produce quick and straightforward programs in text mode.

Text Windows offer an excellent path for the beginning programmer, or for anyone who needs a procedural code model. As the name implies, they display only fixed-width text. Further, only one Text Window may exist at a time. If you need snazzy graphics, more specialized fonts, multiple windows, or a GUI interface, you should look to GRAPHIC WINDOWS and GRAPHIC CONTROLS instead.

Text Window methods are accessed like any other object. The object name TXT is followed by a period separator, and the name of the method or property:

```
TXT.Cell = RowValue&, ColumnVal&
```

Text Window methods which return a value may be used in two forms, a statement with a TO clause, or a function which may be used as a term in an expression:

```
TXT.Row TO RowVar&
RowVar& = TXT.Row
```

The two examples above are functionally identical. The choice is simply a matter of your personal preference. If you use the second form (as a function which returns a value), it can be a term in any expression of any complexity.

Most PowerBASIC functions specify graphic and pixel positions as x,y (the horizontal term first, then the vertical term). However, for compatibility with most current and prior versions of BASIC (PowerBASIC included), the functions which reference text rows and columns name the vertical term first (rows, columns).

Text Windows handle text wrapping and auto-scrolling much like a typical Console Window. When printing exceeds the end of a line, the print position wraps to the first column of the next row. When printing exceeds the last row, the entire page is scrolled to open a new line at the bottom.

In order to use the TXT object successfully, you must use care to first create a Text Window in your program. To do this, you can execute the TXT.WINDOW method.

All Text Windows are stable. They cannot be closed unexpectedly by the user, so there are no surprises when you find you are trying to print to a window which no longer exists. There is no Close Box, no System Menu, nor is ALT-F4 recognized as a close command. They can only be closed by executing TXT.END, or by terminating the entire application.

TXT METHODS

TXT.CELL

Syntax

```
TXT.CELL = RowValue&, ColValue&
TXT.CELL TO RowVar&, ColVar&
TXT.COL TO ColVar&   <or>   ColVar& = TXT.COL
TXT.ROW TO RowVar&   <or>   RowVar& = TXT.ROW
```

Remarks

TXT.CELL is used to set or retrieve the cursor position, based upon the row and column position of a Text Cell. That is the row and column position where the next printed text will be displayed. *RowValue&* specifies the horizontal screen row (starting at 1) at which to position the cursor. *ColValue&* specifies the vertical screen column (starting at 1) at which to position the cursor. Since row and column numbers start at one (1), the upper left corner of the Text Window is considered to be cell 1,1.

The first form of TXT.CELL moves the cursor to the desired row and column. If a value given is zero (0), that parameter is ignored and that position is not changed. The second form of TXT.CELL retrieves the current cursor position, and assigns the values to the variables specified by *RowVar&* and *ColVar&*.

The last two forms allow you to retrieve just a single value, either row or column, and are supported in both statement and function form.

TXT.CLS

Syntax

```
TXT.CLS
```

Remarks

The text window is cleared, and the caret (next print position) is moved to the upper left corner (row 1, column 1).

TXT.COLOR

Syntax

```
TXT.COLOR = RGBColor&
```

Remarks

TXT.COLOR is used to change the foreground color of new text drawn with TXT.PRINT. Existing text on the Text Window is not changed. PowerBASIC includes many built-in RGB color equates which may be used here, like %RGB_RED, %RGB_BLUE, etc.

TXT.END

Syntax

```
TXT.END
```

Remarks

The Text Window currently attached to your program is destroyed and detached from the process. No errors are generated, even if no Text Window is currently attached.

TXT.INKEY$

Syntax

```
TXT.INKEY$ TO InkeyVar$
InkeyVar$ = TXT.INKEY$
```

Remarks

Reads a keyboard character if one is ready. TXT.INKEY$ returns a

of 0 or 1 characters that reflects the status of the keyboard buffer for the current text window. A null string (LEN=0) means that the buffer is empty - no key was pressed.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.INKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.INSTAT

Syntax

```
TXT.INSTAT TO InStatVar&
InstatVar& = TXT.INSTAT
```

Remarks

Determines whether a keyboard character is ready. The variable receives the keyboard buffer status for the current text window. The value assigned is TRUE (non-zero) if a keyboard character is ready to be retrieved, or FALSE (zero) if not.

TXT.INSTAT does not remove the character from the buffer, so repeated execution will continue to return TRUE until the character is read with TXT.INKEY$, TXT.LINE.INPUT, etc.

TXT.LINE.INPUT

Syntax `TXT.LINE.INPUT(["prompt",] StringVar)`

Remarks Reads an entire line from the keyboard into a string variable, ignoring any delimiters which may be embedded. The prompt is an optional string constant or string equate. Upon execution, the prompt is displayed and the program waits for keyboard input. Keystrokes are accepted until the user presses ENTER, at which time the resulting string is stored into the *StringVar*.

The *StringVar* may be a fixed-length, nul-terminated, or a dynamic string. For fixed-length and nul-terminated strings, keyboard input longer than the string is truncated to fit. Dynamic strings receive the complete keyboard input without truncation. *StringVar* may not be a UDT variable, although fixed-length and nul-terminated UDT member variables are allowed.

TXT.PRINT

Syntax `TXT.PRINT([ExprList] [SPC(n)] [TAB(n)] [,] [;]...)`

Remarks Write text data to the TEXT WINDOW at the current caret location. The TXT.PRINT method has the following parts, which may occur in any order and quantity:

ExprList: Numeric and/or string expression(s) to be written to the TEXT WINDOW.

SPC(*n*)	An optional function used to insert *n* spaces into the printed output. Multiple use of the SPC argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.
TAB(*n*)	An optional function used to tab to the *n*th column before printing an expression. Multiple use of the TAB argument is permitted in TXT.PRINT, such as positions between expressions. Values of *n* less than 1 are ignored.

; and , are special characters that determine the position of the next text item printed. A semicolon (;) means the next text item is printed immediately; a comma (,) means the next text item is printed at the start of the next print zone. Print zones begin every 14 columns.

If the final argument of TXT.PRINT is a semicolon or comma, the caret position is maintained at the current location, rather than the default action of moving the print position to the start of the next line. For example:

```
TXT.PRINT "Hello";
TXT.PRINT " world!";
```

...produces the contiguous result "Hello world!"

If you omit all arguments, TXT.PRINT prints a blank line. Printing always begins at the current caret position.

Any control codes, such as Carriage Return, Line-Feed and Backspace are not interpreted. They will display on the screen as symbols.

It is not possible to print a User-Defined Type (UDT), a Variant, an object variable, or an entire array. Individual member values must be extracted with the appropriate function before they can be displayed.

TXT.WAITKEY$

Syntax `TXT.WAITKEY$ [TO WaitVar$]`

***WaitVar$*** **= TXT.WAITKEY$**

Remarks Reads a keyboard character, waiting until one is ready. It removes the character from the keyboard buffer for the Text Window, and optionally assigns it to the string variable. If the TO clause is omitted, the keyboard character is discarded.

TXT.WAITKEY$ returns a string of 0 or 1 characters that reflects the status of the keyboard buffer for the Text Window. A null string (LEN=0) means that there was an error, such as the case when no Text Window currently exists.

A string length of one means that a standard key was pressed and the string contains the character. A value between 1 and 31 indicates a control code.

TXT.WAITKEY$ only processes standard characters. Extended keys, like function keys and the insert key, are ignored.

TXT.WINDOW

Syntax **TXT.WINDOW(*Cap$*, *x*, *y* [,*Rows*, *Cols*]) TO *hWin***

Remarks A new Text Window is created and attached to your program. The size of the Window is determined by rows and cols, or defaults to 25 rows and 80 columns. Subsequent TXT Methods will act upon this newly created Text Window.

If the Text Window is created successfully, the handle will be assigned to the variable specified by *hWin*. If it fails, the value zero (0) will be assigned instead. If you try to create a Text Window while another still exists, it will fail. In this case, you must first destroy the prior Text Window, as only one may exist at a time.

The parameters *x* and *y* specify the requested location of the window, relative to the upper left corner of the desktop. The parameters are always given in pixels. Rows and columns optionally specify the size of the window, given in the number of characters which will fit within the borders. If not given, the method defaults to 25 vertical rows by 80 horizontal columns.

See also DIALOG NEW, GRAPHIC WINDOW, INPUTBOX$, MSGBOX

TYPE/END TYPE block

TYPE/END TYPE block

Purpose Define a User-Defined Data Type (UDT), containing one or more member elements.

Syntax

```
TYPE MyType [BYTE | WORD | DWORD | QWORD] [FILL]
  [MemberName [(subscripts)] AS] TypeName
  [MemberName [(subscripts)] AS TypeName]
  [...]
END TYPE
```

Remarks The TYPE statement has the following parts:

TYPE The beginning of a User-Defined Type definition.

MyType The name of the User-Defined Type, which must conform to standard variable naming conventions.

Member alignment

TYPE definitions may optionally specify an alignment of BYTE (the default), WORD, DWORD, or QWORD, as well as FILL characteristics. With standard alignment, each member of a Type Structure will be located on the specified boundary. For example, with DWORD, up to 3 bytes may be skipped between members to accomplish alignment.

However, when a user-defined type is defined as a member of a larger user-defined type, this "sub-type" retains its original size and alignment, just as first declared.

BYTE Each member will be aligned on a BYTE boundary - no padding or alignment is applied to the structure. This is the default alignment method.

WORD — Each member will be aligned on a WORD boundary. Any odd byte between members of TYPE will be automatically skipped and ignored. The UDT structure may also be padded with one trailing byte to ensure the total structure size is a multiple of 2 bytes.

DWORD — Each member will be aligned on a DWORD boundary. Up to three bytes will be skipped to accomplish this alignment. The UDT structure is also padded with up to three trailing bytes to ensure the total structure size is a multiple of 4 bytes.

QWORD — QWORD alignment is included for compatibility with Windows, it cannot be fully implemented in a 32-bit operating system. With QWORD, individual members are 64-bit aligned for the appropriate structure size, but variables of that type may only be aligned on 32-bit boundaries, as stack pointer alignment is not guaranteed.

FILL — If the FILL option is specified, such as TYPE xxx DWORD FILL, the following rules apply:

1. No bytes are skipped if the next member of the Type will fit entirely into that space to be skipped.
2. Fixed-length strings are considered to be an array of bytes, so no bytes are skipped preceding them.
3. The total size of an array is considered to determine if FILL should affect its placement within the structure. For example, with DWORD FILL, an array of two integers would be started on a 4-byte boundary, even if two or three bytes must be skipped.

Type members

MemberName — The name of a member of the User-Defined Type. This too must follow the standard variable naming conventions.

subscripts — The dimensions of a member array. Arrays of one and two dimensions are supported, but must be defined with constant or numeric literal values. That is, the total size of a UDT must be known at compile-time, so items like dynamic strings, which vary in size, cannot be part of a TYPE structure. A STRING PTR can, however, since a pointer is implemented as a DWORD.

Like conventional arrays, the default lower array boundary is zero, but positive non-zero values may be used to specify a specific range of subscript index values for the array, separated from the upper array boundary subscript with the TO keyword. Additionally, both the lower and upper subscript index values must be zero or greater (ie, negative subscript values are not permitted). Examples of valid syntax follow:

```
TYPE MYTYPE
  id AS INTEGER                 ' Scalar UDT member
  Styles(6)          AS DWORD '  7 elements (0 TO 6)
  Yrs(1980 TO 2010) AS LONG  ' 31 elements
  Team(100 TO 101)  AS BYTE  '  2 elements
  Rating(1 TO 10)   AS DWORD ' 10 elements
  X(1 TO 5, 0 TO 5) AS EXT   ' 30 elements (5x6)
  Y(4,3)            AS QUAD  ' 20 elements (5x4)
END TYPE
```

Individual UDT structures can be up to 16 MB each. A single member element of a UDT may also occupy the entire 16 MB. For example, arrays within a UDT, nul-terminated strings, and fixed-length strings. UDT member arrays are not resizable at runtime. Additionally, the

cannot be used directly on a UDT member array. Instead, use DIM..AT to declare a conventional array at the same memory address as the UDT member array, and the ARRAY statement can then be used on that array.

TypeName — One of the supported data types, including User-Defined Types and Unions, with the exception of arrays.

END TYPE — Marks the end of the User-Defined Type definition.

It is often very convenient to be able to refer to several different types of things as a single unit or data structure. For example, in an accounting program, an account number and amount are part of what makes up a single journal entry. The TYPE/END TYPE block statements make it easy to create a single UDT that holds such information.

```
TYPE JournalType DWORD    ' type name and alignment
  AccountNumber AS LONG  ' member name and data type
  Amount        AS CUR   ' this is another one
END TYPE                 ' end of type declaration

DIM JournalEntry AS JournalType ' declare a record
```

TYPE/END TYPE blocks must be defined outside of a Sub, Function, or Class and may be defined only once in any program. It is usually easiest to put your TYPE/END TYPE block definitions in an Include file and use the #INCLUDE metastatement in any module that may need to use them.

TYPE/END TYPE blocks do not declare any variables; instead, they simply define a new type. You can declare variables of that type using the DIM or REDIM statements, or any statement that lets you use an AS clause:

```
DIM TypeVariable as TypeVariableType
```

Once you have a User-Defined Type variable declared, you can access its member elements using the following format:

```
TypeVariable.Element
```

For example, to change the account number in the *JournalEntryType* type, you might use a statement like:

```
JournalEntry.AccountNumber = 1000
```

A User-Defined Type can be used like any built-in PowerBASIC type. For example, you can define an array of record variables:

```
DIM JournalEntries(1 TO 100) AS JournalEntryType
```

…or even create a procedure that accepts a record variable:

```
SUB PrintJournalEntry(aJournalEntry AS JournalEntryType)
  ' Print journal
END SUB
```

You can also use pointers in a TYPE definition. *Note* that the first member in the next example is auto-aligned to start on a DWORD boundary, and three bytes are skipped so that the second member is also aligned on a DWORD boundary:

```
TYPE MyType DWORD
  Count AS BYTE     ' Aligned to a DWORD boundary
  y AS INTEGER PTR ' Aligned to next DWORD boundary
  z AS STRING PTR
END TYPE
```

Since pointers are stored as a DWORD, their length is 4 bytes when used in a TYPE/END TYPE, regardless of the length of their target. To access the target of a pointer, you must place the at-sign in front of the TYPE/END TYPE member, not the name of the TYPE itself:

```
iResult% = @MyType.y    ' Invalid
iResult% = MyType.@y    ' Valid
```

You can also declare a variable that is a pointer to a TYPE:

```
TYPE MyData
  Val1 AS INTEGER
  Val2 AS INTEGER
  Val3 AS INTEGER
  Val4 AS INTEGER
END TYPE

DIM Info AS MyData PTR
Info = VARPTR(YourData)
```

```
Message$ = HEX$(@Info.Val1) + $CRLF + _
           HEX$(@Info.Val2) + $CRLF + _
           HEX$(@Info.Val3) + $CRLF + _
           HEX$(@Info.Val4)
```

Note that the target specifier is in front of the TYPE name since it is the pointer. Val1, Val2, Val3, and Val4 represent offsets from that pointer. PowerBASIC does support a pointer within a structure pointer, but you should be *very* careful in their use. Changing the structure pointer itself could make all member pointers invalid. See the topic on pointers for more information.

Bit Variables

TYPE structures may contain bit variables, which are named BIT (unsigned values) or SBIT (signed values). Each bit variable may occupy from 1 to 31 bits, and they may be packed one after another up to a total of 32 bits per bit field. The size of a bit variable is defined as follows:

```
var AS BIT * nlit [IN BYTE|WORD|DWORD]
```

…where the term "* nlit" defines the number of bits (1 to 31), and the optional term "IN BYTE|WORD|DWORD", if present, defines the start of a new bit field of 1, 2, or 4 bytes. For example:

```
TYPE ABCD
  Valu2 AS BIT  * 31 IN DWORD
  Sign1 AS SBIT * 1
  nybl2 AS BIT  * 4 IN BYTE
  nybl1 AS BIT  * 4
END TYPE
```

The example TYPE structure above is 5 bytes in size, containing a 4-byte bit field and a 1-byte bit field. In this case, each contains two bit-variables of varying size. The range of values which may be stored depends upon the number of bits available. For example, "BIT * 4" has a range of 0 to 15, "SBIT * 1" has a range of -1 to 0, and "SBIT * 5" has a range of -16 to +15.

Structures within structures

Structures (TYPE/UNION) may be embedded within another structure, for simplification in referencing deeply nested items, by simply stating the structure name alone at the appropriate position. The internal alignment of the member structure is precisely maintained regardless of other alignment specifications, to foster inheritance issues. For example:

TYPE ABCD3	TYPE **ABCD2**	UNION **ABCD1**
A AS LONG	D AS DWORD	F AS DWORD
ABCD2	E AS DOUBLE	G AS LONG
C AS LONG	**ABCD1**	H AS SINGLE
END TYPE	END TYPE	END UNION

In this case, you could access the lone Single-precision float member of this structure very simply. Assuming DIM X AS ABCD3, you could reference the Single-precision Union member with the statement X.H, instead of the extended syntax X.ABCD2.ABCD1.H

For related information, please refer to the UNION/END UNION and User-Defined Types and Unions sections.

Restrictions

When measuring the size of a padded (aligned) UDT structure with the LEN or SIZEOF statements, the measured length includes any padding that was added to the structure. For example, the following UDT structure:

```
TYPE LengthTestType DWORD
  a AS INTEGER
```

```
END TYPE
' more code here
DIM abc AS LengthTestType
x& = LEN(abc)
```

Returns a length of 4 bytes in *x&*, since the UDT was padded with 2 additional bytes to enforce DWORD alignment. Note that the LEN and SIZEOF of individual UDT members will return the true size of the member without regard to padding or alignment. In the previous example, LEN(abc.a) returns 2.

Individual UDT structures can be up to 16 MB each. Arrays within a UDT, nul-terminated strings and fixed-length strings may occupy the full 16 MB structure size limit.

Field strings and dynamic strings cannot be used in UDT or UNION structures. Attempting to do so results in a compile-time Error 485 ("Dynamic/Field strings not allowed").

See also DIM, LEN, REDIM, LET (with Types), SIZEOF, TYPE SET, UNION/END UNION, User-Defined Types, Unions

Example

```
TYPE JournalEntryType
  AccountName    AS STRING * 20
  AccountNumber  AS LONG
  Amount         AS CUR
END TYPE

DIM JournalEntry AS JournalEntryType

JournalEntry.AccountName   = "Joe Smith"
JournalEntry.AccountNumber = 7467047&
JournalEntry.Amount        = 42.01@
' process journal entry here
JournalEntry.AccountNumber = 705233476&
JournalEntry.Amount        = 69.35@
' process journal entry here
```

TYPE SET statement

TYPE SET statement

Purpose Assign the value of a User-Defined Type or byte string expression into another User-Defined Type variable.

Syntax `TYPE SET typevar = {typevar | ByteStringExpr$} [USING ustring_expression]`

Remarks TYPE SET is primarily designed to assign the value of a User-Defined Type (UDT) to a different class of User-Defined Type. Additionally, TYPE SET can be used to assign a string expression (*ByteStringExpr$*) to a UDT, though it is generally not appropriate to assign a wide Unicode string.

USING Any Byte positions remaining after the assignment are filled (padded) in the target *typevar* with the first character of the USING string expression, or binary zeros if not specified.

See also CSET, CSET$, LET (with Types), LSET, LSET$, RSET, RSET$, TYPE/END TYPE

Example

```
TYPE udt1
  x AS STRING * 12
  y AS LONG
  z AS INTEGER
END TYPE

TYPE udt2
  a(1 TO 18) AS BYTE
```

```
END TYPE

FUNCTION PBMAIN
  DIM u1 AS udt1
  DIM u2 AS udt2

  u1.x = "ABC"
  TYPE SET u2 = u1
  a$ = CHR$(u2.a(1), u2.a(2), u2.a(3))

  TYPE SET u2 = "1" USING "2"
  b$ = CHR$(u2.a(1), u2.a(2), u2.a(3))
END FUNCTION
```

Result

```
a$ contains "ABC"
b$ contains "122"
```

UBOUND function

UBOUND function

Purpose Return the largest possible subscript (boundary) for an array's specified dimension.

Syntax

```
y = UBOUND(array [(dimension)])
y = UBOUND(array, dimension)
```

Remarks *array* is the array of interest. *dimension* is an

value or expression from 1 up to the number of dimensions in *array*; it specifies which dimension's upper bound value will be returned. If you omit *dimension*, it defaults to 1 (the first dimension). To find the lower bound of an array's dimension, use the LBOUND function. Use LBOUND and UBOUND together to determine an array's size. UBOUND of an undimensioned array returns -1, so that `UBOUND(array) - LBOUND(array) + 1` yields zero (0) for such an array.

Restrictions UBOUND cannot be used on arrays *within* User-Defined Types.

See also ARRAYATTR, DIM, LBOUND, REDIM

Example

```
' Dimension an array with lower and upper bounds
DIM MyArray%(1900 TO 2000,5 TO 10)

' print out the values of the array
Message$ = "The array's first dimension is from" + _
           STR$(LBOUND(MyArray%(1))) + "to" + _
           STR$(UBOUND(MyArray%(1)))
Message$ = "The array's second dimension is from" + _
           STR$(LBOUND(MyArray%(2))) + "to" + _
           STR$(UBOUND(MyArray%(2)))
```

Result

```
The array's first dimension is from 1900 to 2000
The array's second dimension is from 5 to 10
```

UCASE$ function

UCASE$ function

Purpose Return an all-uppercase (capitalized) version of a

.

Syntax

```
s$ = UCASE$(string_expression [,ANSI | OEM])
```

Remarks UCASE$ returns a string equivalent to *string_expression*, except that lowercase letters in *string_expression* are converted to uppercase. The optional ANSI or OEM parameter specifies whether the conversion is made using the ANSI charset for the system, or the original IBM OEM charset. If no charset is specified, PowerBASIC for Windows uses the system ANSI charset, while PB/CC uses the IBM OEM charset. Only "International" characters in the range of CHR$(128) to CHR$(255) are affected by this parameter.

The OEM charset is based upon the original IBM OEM charset to ensure compatibility with programs written for all previous versions of the PowerBASIC compiler.

See also ASC, LCASE$, MCASE$

Example
```
x$ = UCASE$("Beware of cats!")
```

Result
```
BEWARE OF CATS!
```

UCODE$ function

UCODE$ function

Purpose Translates ANSI bytes into Unicode bytes.

Syntax
```
a$ = UCODE$(AnsiStrExpression [,CodePage&])
```

Remarks This version of PowerBASIC handles all conversions between ANSI strings and UNICODE strings automatically. For example:

```
MyWideString$$ = MyAnsiString$
```

In this case, the ANSI characters are transparently converted to WIDE UNICODE characters when they are stored in *MyWideString$*. You should not insert a UCODE$ function here. The simple fact that the variables are of differing types (ANSI/WIDE) causes the compiler to make all conversions for you, whenever they are needed.

Of course, this automatic conversion was not available in previous versions of the compiler. In the past, there were no WIDE UNICODE variables offered, so it was necessary to force wide characters into standard byte strings when UNICODE was needed. The ACODE$ and UCODE$ functions are used for this purpose alone: to support legacy programs which calculated strings in this fashion.

New PowerBASIC programs and updates to your older PowerBASIC programs should use the new WIDE UNICODE variables which are now available.

UCODE$ presumes that the *AnsiStrExpression* contains ANSI byte characters stored in an ANSI byte string. It converts them into WIDE UNICODE characters and returns them as an ANSI byte string. To convert a UNICODE byte string into an ANSI byte string, use the ACODE$ function.

If the optional parameter *CodePage&* is present, it represents the code page to be used for the conversion process. If not given, the default code page for the locale of the executing computer is used.

Unicode strings require two bytes to represent a Unicode character, whereas ANSI strings (the native PowerBASIC string format) use one byte to represent a character. Therefore, UCODE$ returns a string that has double the byte count of the ANSI string, yet represents the same number of characters.

See also ACODE$, UCODEPAGE

UCODEPAGE statement

Keyword Template

Purpose

Syntax
Remarks
See also
Example

UCODEPAGE statement IMPROVED

Purpose Set the default codepage used for ANSI / UNICODE conversions.

Syntax `UCODEPAGE ANSI|OEM|NumExpr [TO PrevPage&]`

Remarks PowerBASIC will make many conversions between ANSI and UNICODE (wide character) . UCODEPAGE specifies the CodePage to be used for these translations. The default is UCODEPAGE ANSI which will use the system ANSI codepage for your computer. UCODEPAGE OEM will use the system OEM codepage for your computer, while a expression can specify a particular CodePage of your choice.

If the optional TO clause is used, the number of the previous default CodePage is assigned to the long integer variable specified by *PrevPage&*. By saving the previous codepage, you can later restore it, if that's appropriate.

This statement does not change the CodePage in use by your computer. It tells which codepage PowerBASIC should use for ANSI/UNICODE conversions.

By default, the system ANSI CodePage, is used to map the character translation, and this generally works very well, as it represents the usual codepage for your primary language. However, if you are compiling a CONSOLE application which makes use of the high-order ANSI codes, CHR$(128) through CHR$(255) for line drawing and a few international characters, you should declare an OEM CodePage by placing UCODEPAGE OEM at the start of your MAIN function.

The CodePage specification is maintained on a thread-by-thread basis. At program start, the default is the system ANSI CodePage. If a new is launched, it inherits the CodePage in use by the main thread.

See also ACODE$, UCODE$

UDP CLOSE statement

UDP CLOSE statement

Purpose Close a previously opened UDP socket that was created with the UDP OPEN statement.

Syntax `UDP CLOSE [#] fNum&`

Remarks Close the previously opened UDP/IP port specified by *fNum&*.

See also TCP and UDP Communication, TCP CLOSE, UDP NOTIFY, UDP OPEN, UDP RECV, UDP SEND

UDP NOTIFY statement

UDP NOTIFY statement

Purpose Designate which UDP/IP events will generate a notification message.

Syntax `UDP NOTIFY [#] fNum&, {SEND | RECV | CLOSE} TO hWnd& AS wMsg&`

Remarks Designates which events (SEND, RECV, and CLOSE) will generate a notification *wMsg&*

message, to be sent to the window/dialog procedure (CALLBACK), identified by the window handle *hWnd&*.

Your program defines the *wMsg&* value, and this value should be equal or larger than %WM_USER + 500, to avoid conflict with common Windows callback message values.

When the nominated Callback Function receives the *wMsg&* notification, the *wParam&* parameter identifies the operating system's handle of the socket (see FILEATTR). The low-order Word of *lParam&* specifies the code of the event (see table below), and the high-order Word of *lParam&* contains the error code (if any).

LO(WORD, *lParam&*)	Definition
%FD_READ	Data is available to be read from the socket.
%FD_WRITE	The socket is ready for data to be written.
%FD_CLOSE	The socket has been closed.

Notification messages do not arrive in unabated or continuous streams. That is, once a particular notification message arrives, it will not be sent again until the initial message is acted upon. For example, if an %FD_READ notification is received for a particular socket, it will not be resent until after a UDP RECV statement is executed.

The Winsock error codes are listed in WINSOCK2.INC, prefixed with `%WSAE`.

See also FILEATTR, TCP and UDP Communication, TCP NOTIFY, UDP CLOSE, UDP OPEN, UDP RECV, UDP SEND

UDP OPEN statement

UDP OPEN statement

Purpose Create a socket for an application to communicate with a UDP server or client using the UDP (connectionless) protocol over Winsock (UDP/IP).

Syntax **`UDP OPEN [PORT p&] AS [#] fNum& [TIMEOUT timeoutval&]`**

Remarks Open a UDP socket (port or service) for UDP communication. *FNum&* is a file number such as #1, or a variable with a value obtained using the FREEFILE function.

PORT If PORT *p&* is specified, the socket is opened as a server that can receive UDP data. Use the UDP NOTIFY statement to receive server notifications from the socket so that the data can be retrieved. Common port numbers include 7 (Echo, see RFC862); 37 (Time, see RFC868); and 123 (NTP - RFC1305).

TIMEOUT The TIMEOUT option allows you to specify how long, in milliseconds (*mSec*), a UDP SEND/RECV operation should wait for completion. If the specified number of milliseconds elapses, the UDP operation will fail, and the ERR system variable will be set to indicate a run-time Error 24 ("Device timeout"). The default timeout is 60000 milliseconds (60 seconds).

See also TCP and UDP Communication, FREEFILE, TCP OPEN, UDP CLOSE, UDP NOTIFY, UDP RECV, UDP SEND

UDP RECV statement

UDP RECV statement

Purpose Receive data from a previously opened UDP port.

Syntax **`UDP RECV [#] fNum&, FROM ip&, pNum&, Buffer$`**

Remarks Receive any bytes from the previously opened UDP port specified by *fNum&*, and place them into *Buffer$*. The IP address that sent the UDP packet is placed into the *ip&* variable, and the port number is placed into the *pNum&* variable.

ip& and *pNum&* may be subsequently used to send data back in response to data received.

UDP RECV is a blocking statement. That is, execution does not continue until either data is retrieved from the socket, or the timeout period expires.

If a timeout occurs, a run-time Error 24 ("Device timeout") is generated and placed in the ERR system variable. See UDP OPEN to specify the UDP socket timeout value.

See also TCP and UDP Communication, TCP RECV, UDP CLOSE, UDP NOTIFY, UDP OPEN, UDP SEND

UDP SEND statement

UDP SEND statement

Purpose Send a

of data through a previously opened UDP socket.

Syntax **UDP SEND [#]** ***fNum&*****, AT** ***ip&*****,** ***pNum&*****,** ***string_expression***

Remarks Write the specified *string_expression* to the UDP/IP port *pNum&* at the IP address specified in *ip&*, using the UDP connection specified by *fNum&*.

See also TCP and UDP Communication, TCP SEND, UDP CLOSE, UDP NOTIFY, UDP OPEN, UDP RECV

UNION/END UNION block

UNION/END UNION statements

Purpose Create a new User-Defined Type definition whose member elements overlap in memory.

Syntax

```
UNION UnionName
   MemberName [(subscripts)] AS TypeName
  [MemberName [(subscripts)] AS TypeName]
  [...]
END UNION
```

Remarks A union is a type - very similar to a User-Defined Type - except that its elements overlap in memory. While this may seem strange at first, it has enormous potential.

For example, say you are designing an accounting program. You want to make it general purpose so it has widespread appeal. But everyone does their accounting differently; for example, some people use account numbers that are plain integral values, while others may use alphanumeric account names. Using a Union makes this easy. Another common use of a Union is variable type conversion. The is best described by way of an example:

```
UNION VarConvert
  iLong  AS LONG
  iDword AS DWORD
  sStr   AS STRING * 4
END UNION

DIM x AS VarConvert, y AS DWORD, z AS STRING
x.iLong = 123456&
y       = x.iDword
z       = x.sStr
```

Like a User-Defined Type, a Union may also contain arrays, and these follow the same rules as User-Defined Type member arrays (see Type Members for syntax rules and additional examples). The following example demonstrates the use of a Union member array:

```
UNION Arrs
  a1(1 TO 1024) AS BYTE
  st AS ASCIIZ * 10
END UNION

FUNCTION PBMAIN
    DIM a AS Arrs
    a.a1(1) = 72
    a.a1(2) = 101
    a.a1(3) = 108
    a.a1(4) = 108
    a.a1(5) = 111
    a.a1(6) = 33
    ' At this point, a.st contains "Hello!"
END FUNCTION
```

Bit Variables

UNION structures may contain bit variables, which are named BIT (unsigned values) or SBIT (signed values). Each bit variable may occupy from 1 to 31 bits, and they may be packed one after another up to a total of 32 bits per bit field. The size of a bit variable is defined as follows:

```
var AS BIT * nlit [IN BYTE|WORD|DWORD]
```

…where the term "* nlit" defines the number of bits (1 to 31), and the optional term "IN BYTE|WORD|DWORD", if present, defines the start of a new bit field of 1, 2, or 4 bytes. For example:

```
UNION ABCDE
  Odd1 AS BIT * 1 IN DWORD
  Value1 AS LONG
END UNION
```

The example UNION structure above is 4 bytes in size, containing a 1-byte bit field and a 4-byte LONG.

```
UNION abcde
  Part1 AS BIT * 8 IN DWORD
  Part2 AS BIT * 16
END UNION
```

The example union above is 4 bytes in size, containing an 8-bit field and an overlapping 16-bit field.

Structures within structures

Structures (TYPE/UNION) may be embedded within another structure, for simplification in referencing deeply nested items, by simply stating the structure name alone at the appropriate position. The internal alignment of the member structure is precisely maintained regardless of other alignment specifications, to foster inheritance issues. For example:

TYPE ABCD3	TYPE **ABCD2**	UNION **ABCD1**
A AS LONG	D AS DWORD	F AS DWORD
ABCD2	E AS DOUBLE	G AS LONG
C AS LONG	**ABCD1**	H AS SINGLE
END TYPE	END TYPE	END UNION

In this case, you could access the lone Single-precision float member of this structure very simply. Assuming DIM X AS ABCD3, you could reference the Single-precision Union member with the variable name X.H, instead of the extended syntax X.ABCD2.ABCD1.H

Restrictions A Union can contain elements of dissimilar sizes. The size of a Union structure is always determined by the longest member element. This is usually an important consideration when using a Union within another Union or UDT structure, in order to determine the size of the final structure.

For related information, please refer to the TYPE/END TYPE, User-Defined Types and Unions sections.

Field strings cannot be used in UDT or UNION structures. Attempting to do so results in a compile-time Error 485 ("Dynamic/Field strings not allowed").

See also DIM, LEN, LET (with Types), SIZEOF, TYPE/END TYPE, User-Defined Types, Unions

Example

```
UNION AccountUnion
  AccountNumber  AS LONG
  AccountName    AS STRING * 16
END UNION

TYPE JournalEntryType
  Account  AS AccountUnion
  Amount   AS CUR
END TYPE

DIM JournalEntry AS JournalEntryType

JournalEntry.Account.AccountName = "Smith"
JournalEntry.Amount = 123.01@
' process journal entry here
JournalEntry.Account.AccountNumber = 1001
JournalEntry.Amount = -1.99@
```

UNLOCK statement

UNLOCK statement

Purpose Remove locks placed on a file to permit other threads, processes, and applications to access the locked sections of the file.

Syntax **UNLOCK [#] *filenum&* [, {*record&&* | *start&&* TO *finish&&*}]**

Remarks UNLOCK restores access to a record, range of records, byte, or range of bytes locked by the LOCK statement, in file opened as file number *filenum&*.

If the file was opened in random-access mode, *record&&*, *start&&*, and *finish&&* specify record numbers.

When used with binary mode files, *record&&*, *start&&*, and *finish&&* specify byte positions, starting from either one (the default) or zero, depending on the BASE setting given when the file was Opened.

If a record is specified, only that record (or byte) is unlocked. Otherwise, a range of records (or bytes) is unlocked, from *start&&* to *finish&&*. If no records are specified, or if the file was opened in sequential mode, the entire file is unlocked.

All records (or bytes) to be unlocked must have been previously locked using the LOCK statement. Multiple locks may be placed on a file, and locks may be unlocked in any order. However, the parameters used for each UNLOCK statement must exactly match those used for the previous corresponding LOCK statement.

All locked records (or bytes) must be unlocked using the UNLOCK statement before the file can be closed.

If an unlock attempt fails, PowerBASIC sets the ERR system variable to reflect a run-time Error 70 ("Permission denied"), or Error 75 ("Path/file access error").

See also LOCK, OPEN

Example See the example for LOCK.

UNWRAP$ function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

UNWRAP$ function New!

Purpose Remove paired characters from the beginning and end of a

.

Syntax ***s$*** **= UNWRAP$(*StringExpression*, *LeftChar$*, *RightChar$*)**

Remarks The UNWRAP$ function removes the characters in *LeftChar$* from the beginning of *StringExpression*, if there is an exact match. It then removes the characters in *RightChar$* from the end, if there is an exact match. The remaining character are then returned. For example:

```
UNWRAP$("<MyWord>", "<", ">")  returns  "MyWord"
```

UNWRAP$ is particularly useful for removing parentheses, quotes, brackets, etc. from a text item.

See also EXTRACT$, LTRIM$, MID$, REMOVE$, REPLACE, RTRIM$, SHRINK$, TRIM$, WRAP$

USING$ function

USING$ function

Purpose Format one or more

or expressions, based upon the contents of the format mask string.

Syntax ***sResult$*** **= USING$(*fmtmask$*, *expr* [, *expr* [, ...]])**

Remarks The rules of formatting are based upon the PRINT USING statement supported in many DOS versions of BASIC, including PowerBASIC for DOS.

However, since it is implemented as a function, it allows far more versatility in that it is not necessary to output a value to gain the benefit of this unique functionality. Also, USING$ offers a wider range of applications than FORMAT$ because it can format both numeric and string expressions, and can take multiple arguments.

fmtmask$ A string expression, string variable or string literal consisting of format characters that will determine how the complete expression should be formatted. This expression is termed the *mask*. There may be as many format masks in *fmtmask$*, arranged in the same order as the *expr* arguments are specified. See the examples below for more information.

expr A string or numeric expression, variable, or literal value to be formatted. The mask characters available depend on whether *expr* is a string or numeric.

Character **Definition**

(string expr)	**When *expr* is a string, the following format codes apply within *fmtmask$*:**
!	The first character of the string is returned.
&	The entire string is returned.
\\	The first two characters are returned.
\ \	If backslashes enclose *n* spaces, *n* + 2 characters of the string expression are returned.
_	Escape (underscore) character. The following character is interpreted as a literal character instead of a mask format character.
(numeric expr)	**When *expr* is numeric, the following format codes apply within *fmtmask$*:**
#	A numeric digit position, which is space-filled to the left, and zero-filled to the right of the decimal point. If the number is negative, a minus sign occupies a digit position.
.	The decimal point is placed at this position.
,	A numeric digit position, which signifies that whole number digits should be displayed with a comma each three digits.
$$	Two numeric digit positions which cause a dollar sign to be inserted immediately before the number.
**x*	Two numeric digit positions which cause leading blank spaces in the field to be replaced with the character in the second position of the pair "*x*" (where "x" represents your own choice of character). For example, two asterisks "**" will convert leading spaces to asterisks, and "*=" converts leading spaces to equals characters, etc. The **x* mask characters also act as two digit (#) placeholders. Your mask must contain at least three characters to use this.
+	A plus at the start of the field causes the sign of the value (+ -) to be inserted before the number. A plus at the end of the field causes the sign of the value (+ -) to be added after the number.
-	A minus at the end of the field causes a minus signed to be added after a negative number, or a space to be added after a positive number. A minus at the start of the field is treated as a literal character, which is always inserted.
^	Numbers can be formatted in scientific notation by including three to six carets (^) in the format string. Each caret corresponds to a numeric digit position in the exponent, one for E, one for the exponent sign, and one to four for the actual digits of the exponent value.
_	Escape (underscore) character. The following character is interpreted as a literal character instead of a mask format character. Therefore, to include a literal underscore character in the format mask, use two underscore characters.
	All characters in the format mask string that are not identified above are copied into the output string just as they are encountered. You can override or *escape* any special format code by preceding it with an underscore character (_) and it will be copied as any other literal character. This provides the flexibility to include literal string text within the formatted return string.

Restrictions The returned string is limited to an absolute length limit of 1024 bytes.

By specifying a single mask in fmtmask$, all *expr* arguments are subjected to the single mask. See the examples below.

If there are fewer *expr* arguments than matching format masks in fmtmask$, parsing of the *fmtmask$* halts after the last referenced mask position, and subsequent characters in *fmtmask$* are ignored. This is consistent with the behavior of PRINT USING$ in PB/DOS.

If a numeric argument overflows its mask (i.e., there are more digits than digit positions), the resulting string will occupy as many spaces as needed to represent the number. In such cases, PB/DOS includes a leading "%" symbol to indicate the mask overflow;

however, PowerBASIC for Windows does not return the additional "%" overflow character.

The semicolon (;) and zero (0) characters are reserved for future use, so it would be prudent to escape such literal characters in USING$ masks to maintain future compatibility.

See also GRAPHIC PRINT, XPRINT, FORMAT$, STR$

Example

```
a$ = USING$("!", "abc")
' returns "a"

a$ = USING$("You owe $$#,.##", 12345.67@)
' returns "You owe $12,345.67

DIM p AS BYTE PTR
HOST ADDR "localhost" TO ip&
p = VARPTR(ip&)
a$ = USING$("#_.#_.#_.#", @p, @p[1], @p[2], @p[3])
' returns "127.0.0.1"

a$ = USING$("&=#.##############", "Pi", ATN(1)*4)
' returns "Pi=3.14159265358979"

a$ = USING$("!", "AX", "BX", "CX")
' returns "ABC"

a$ = USING$("$#.##_,", 1,20,300,4)
' returns "$1.00,$20.00,$300.00,$4.00,"

a$ = USING$("$*=#####.##_,",1,20)
' returns "$======1.00,$=====20.00,"
```

Utf8ToChr$ function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

Utf8ToChr$ function New!

Purpose Translates a byte string of OEM characters into ANSI/WIDE characters.

Syntax `a$$ = Utf8ToChr$(UtfExpr$)`

Remarks *UtfExpr$* contains a series of bytes in UTF-8 format. Utf8ToChr$ translates it into either ANSI multi-byte equivalent characters or WIDE (16-bit) Unicode characters, depending upon the context of the source code. PowerBASIC will always choose the correct form with no intervention needed by the programmer.

See also ChrToOem$, ChrToUtf8$, OemToChr$

VAL function

VAL function IMPROVED

Purpose Convert a text

to a value.

Syntax ***y* = VAL(*string_expression* [, *offset*])**

Remarks The VAL function converts a string argument to a number. If the optional Offset parameter is included, it indicates the position in the string where the conversion should begin. If not given, it defaults to one (1), and begins at the first character. Leading white-space characters (spaces, tabs, carriage-returns, and linefeeds) are skipped and ignored. Evaluation of the number continues until a non-numeric character is found, or the end of the string is reached. If no number is found, the VAL() function returns zero (0). Format characters (like commas) are not allowed, and will cause early termination of the evaluation.

VAL interprets the letters "e" and "d" (and "E" and "D") as the symbols for exponentiation and scientific notation:

```
i& = VAL("10.101e3") ' 10101 ~ 10.101*(10^3)
j& = VAL("2D4")      ' 20000 ~ 2 * (10 ^ 4)
```

Hexadecimal, Binary and Octal conversions

VAL can also be used to convert string arguments that are in the form of Hexadecimal, Binary and Octal numbers. Hexadecimal values should be prefixed with "&H" and Binary with "&B". Octal values may be prefixed "&O", "&Q" or just "&". If the *string_expressio* contains a leading zero, the result is returned as an unsigned value; otherwise, a signed value is returned. For example:

```
i& = VAL("&HF5F3")        ' Hex, returns -2573 (signed)
j& = VAL("&H0F5F3")       ' Hex, returns 62963 (unsigned)
x& = VAL("&B0100101101") ' Binary, returns 301 (unsigned)
y& = VAL("&O4574514")     ' Octal, returns 1243468 (signed)
```

Valid hex characters include 0 to 9, A to F (and a to f). Valid Octal characters include 0 to 7, and binary 0 to 1.

Use the STR$, DEC$, FORMAT$, and USING$ functions to convert numeric values into decimal strings. Use BIN$, HEX$ and OCT$ to convert them to Binary, Hexadecimal, and Octal representations.

Restrictions VAL stops analyzing *string_expression* when non-numeric characters are encountered. When dealing with Hexadecimal, Binary, and Octal number systems, the period character is classified as non-numeric. This is because PowerBASIC only supports floating-point formats for the decimal number system. VAL accepts the period character as a decimal place for all decimal number system values.

VAL does not analyze trailing type-specifiers for decimal strings. For example, VAL("9.1&") is evaluated as 9.1 rather than 9 because the "&" suffix is treated as a non-numeric character, not a type-specifier. However, type suffixes may be used with binary, octal, and hex values.

See also BIN$, DEC$, FORMAT$, HEX$, OCT$, STR$, USING$, VAL statement

Example

```
Price$ = "$ 15,345.92"
Cost@@ = VAL(REMOVE$(Price$, ANY "$, "))
```

Result

```
15345.92
```

VAL statement

Keyword Template

Purpose

Syntax
Remarks
See also
Example

VAL statement New!

Purpose Convert a text

to a value with additional information.

Syntax **VAL *StrgExpr* [, *offset*] TO *ValueVar* [, *DigitsVar&*, *UnusedVar&*]**

Remarks The VAL statement converts a string argument to a number, but adds additional information about the conversion. Both Leading and trailing white-space characters (spaces, tabs, carriage-returns, and linefeeds) are skipped and ignored. If no number is found, the value zero (0) is returned. Format characters (like commas) are not allowed, and will cause early termination of the evaluation.

VAL interprets the letters "e" and "d" (and "E" and "D") as the symbols for exponentiation and scientific notation:

```
VAL "10.101e3" TO i&    ' 10101 ~ 10.101*(10^3)
VAL "2D4" TO j&         ' 20000 ~ 2 * (10 ^ 4)
```

Hexadecimal, Binary and Octal conversions

VAL can also be used to convert string arguments that are in the form of Hexadecimal, Binary and Octal numbers. Hexadecimal values should be prefixed with "&H" and Binary with "&B". Octal values may be prefixed "&O", "&Q" or just "&". If the *StrgExpr* contains a leading zero, the result is returned as an unsigned value; otherwise, a signed value is returned. For example:

```
VAL "&HF5F3"   TO i&      ' Hex, returns -2573 (signed)
VAL "&H0F5F3"  TO j&      ' Hex, returns 62963 (unsigned)
VAL "&B0100101101"  TO x& ' Binary, returns 301 (unsigned)
VAL "&O4574514"  TO y&    ' Octal, returns 1243468 (signed)
```

Valid hex characters include 0 to 9, A to F (and a to f). Valid Octal characters include 0 to 7, and binary 0 to 1.

Use the STR$, DEC$, FORMAT$, and USING$ functions to convert numeric values into decimal strings. Use BIN$, HEX$ and OCT$ to convert them to Binary, Hexadecimal, and Octal representations.

Offset If the optional Offset parameter is included, it indicates the position in the string where the conversion should begin. If not given, it defaults to one (1), and begins at the first character.

ValueVar A numeric variable which receives the result of the conversion.

DigitsVar An optional long integer variable which receives the count of the number of significant digits found in the evaluation. If this value is zero (0), no valid number was found and zero (0) was also assigned to *ValueVar*.

UnUsedVar An optional long integer variable which receives the count of the unused characters. Since the evaluation skips both leading and trailing white-space, a non-zero value indicates that additional characters of some significance may be present. You can use RIGHT$(StrgExpr, UnUsedVar) to separate the unused characters.

Restrictions VAL stops analyzing string_expression when non-numeric characters are encountered. When dealing with Hexadecimal, Binary, and Octal number systems, the period character is classified as non-numeric. This is because PowerBASIC only supports floating-point formats for the decimal number system. VAL accepts the period character as a decimal place for all decimal number system values.

VAL does not analyze trailing type-specifiers for decimal strings. For example, VAL("9.1&") is evaluated as 9.1 rather than 9 because the "&" suffix is treated as a non-numeric character, not a type-specifier. However, type suffixes may be used with binary, octal, and hex values.

See also BIN$, DEC$, FORMAT$, HEX$, OCT$, STR$ USING$, VAL function

Example

```
s = "The total cost is $145.26."
VAL s, INSTR(s, "$")+1 to i
```

Result

```
145.26
```

VARIANT# function

VARIANT# function

Purpose Returns the numeric value contained in a Variant variable.

Syntax ***numericvar*** **= VARIANT#(*vrntvar*)**

Remarks The value returned by VARIANT# may be any range from BYTE to DOUBLE/QUAD/CURRENCY, depending upon the internal representation used within the Variant.

While Variant variables, by definition, do not offer support for Extended Precision Float data types, you should note that it is possible for a QUAD or CURRENCY value to exceed the precision level offered by a DOUBLE. You should therefore use some judgement in deciding on the

variable type to be used as the destination of this function, based upon the expected return values, and the internal representation, which you can obtain with VARIANTVT.

Restrictions VARIANT# presumes that a valid numeric value is present (not an array); otherwise, the value zero is returned.

See also DIM, LET, OBJECT, LET (with Variants), VARIANT$, VARIANT$$, VARIANTVT

Example

```
DIM vVnt AS VARIANT
vVnt = 999&
a& = VARIANT#(vVnt)
```

VARIANT$/VARIANT$$ function

VARIANT$ / VARIANT$$ function

Purpose Returns the byte

contained in a Variant variable.

Syntax

```
AnsiVar  = VARIANT$(VrntVar)
WideVar  = VARIANT$$(VrntVar)
TypeVar  = VARIANT$(BYTE, VrntVar)
```

Remarks VARIANT$ extracts a string from a variant variable if a dynamic string (VT_BSTR) is found there. If the variant contains any other VT type, an empty string is returned. By definition, a BSTR is a wide Unicode string. It is generally safe to assume this is the case, unless the variant was created by PowerBASIC and you know the internal format is bytes rather than wide Unicode words.

The first form of VARIANT$ converts the wide Unicode contents to ANSI, returning it as an ANSI string. The second form of VARIANT$$ returns the contents directly as a wide Unicode string. Of course, in all assignment and parameter situations, PowerBASIC will automatically handle any conversions needed between ANSI and WIDE string values. For that reason, no additional code should be added to this operation for ANSI/WIDE conversion. Also, keep in mind that the correct choice of function can improve the performance of your program.

BYTE

If the BYTE option is specified, you are telling PowerBASIC that the string contains a set of BYTES rather than wide Unicode words. This would be the case if you stored a User-Defined Type in a variant:

```
LET VariantVar = ThisUDTVar AS STRING
ThatUDTVar = VARIANT$(BYTE, VariantVar)
```

This form of VARIANT$ always returns the contents as an ANSI byte string. This result can be assigned to an ANSI string variable or a User-Defined Type.

Legacy

Older legacy programs were forced to store Unicode characters in an ANSI string variable because wide string variables were not yet available. These programs should continue to use VARIANT$ with ACODE$ and variant assignment with UCODE$ until the program logic is updated to use wide Unicode variables.

See also

DIM, LET, OBJECT, LET (with Variants), VARIANT#, VARIANTVT

Example

```
DIM vVnt AS VARIANT
vVnt = "Hello World"$$
a$ = VARIANT$(vVnt)
```

VARIANTVT function

VARIANTVT function

Purpose

Determine the internal data type of the data stored in a Variant variable.

Syntax

```
numericvar = VARIANTVT(vrntvar)
```

Remarks

The VARIANTVT function returns the internal VT data type stored in the Variant. The entire range of %VT prefixed values are documented by the OLE (COM) specification and are available in WIN32API.INC.

The most important values in this limited context include %VT_EMPTY (=0) and %VT_BSTR (=8), since the others are

formats automatically resolved by the LET (with Variants) statement and VARIANT# function.

Result	Equate	Content Type
0	%VT_EMPTY	An Empty Variant
1	%VT_NULL	Null value
2	%VT_I2	Integer
3	%VT_I4	Long-Integer
4	%VT_R4	Single
5	%VT_R8	Double
6	%VT_CY	Currency
7	%VT_DATE	Date
8	%VT_BSTR	Dynamic String
9	%VT_DISPATCH	IDispatch
10	%VT_ERROR	Error Code
11	%VT_BOOL	Boolean
12	%VT_VARIANT	Variant
13	%VT_UNKNOWN	IUnknown
14	%VT_DECIMAL	Decimal
16	%VT_I1	Byte (signed)

17	%VT_UI1	Byte (unsigned)
18	%VT_UI2	Word
19	%VT_UI4	DWORD
20	%VT_I8	Quad (signed)
21	%VT_UI8	Quad (unsigned)
22	%VT_INT	Long-Integer
23	%VT_UINT	DWord
24	%VT_VOID	A C-style void type
25	%VT_HRESULT	COM result code
26	%VT_PTR	Pointer
27	%VT_SAFEARRAY	VB Array
28	%VT_CARRAY	A C-style array
29	%VT_USERDEFINED	User Defined Type
30	%VT_LPSTR	ANSI
31	%VT_LPWSTR	Unicode string
36	%VT_RECORD	UDT
64	%VT_FILETIME	A FILETIME value
65	%VT_BLOB	An arbitrary block of memory
66	%VT_STREAM	A stream of bytes
67	%VT_STORAGE	Name of the storage
68	%VT_STREAMED_OBJECT	A stream that contains an object
69	%VT_STORED_OBJECT	A storage object
70	%VT_BLOB_OBJECT	A block of memory that represents an obj
71	%VT_CF	Clipboard format
72	%VT_CLSID	Class ID
&H1000	%VT_VECTOR	An array with a leading count
&H2000	%VT_ARRAY	Array
&H4000	%VT_BYREF	A reference value

If a Variant contains a complete array, the Variant type is determined by adding the base type to the arra modifier. That is, for a string array, it would be %VT_BSTR plus %VT_ARRAY (= &H2008).

Quad arrays within Variants are not supported by most versions of Windows. The result from VARIANTVT used to see whether such an array was created properly.

See also DIM, Just what is COM?, OBJECT, LET (with Variants), VARIANT#, VARIANT$, VARIANT$$, What is an anyway?

VARPTR function

VARPTR function

Purpose Return the 32-bit address of a variable.

Syntax `y = VARPTR(variable)`

Remarks VARPTR returns a complete 32-bit address to the specified *variable* as a Double-word (DWORD) value. *variable* is any

, , structure variable (User-Defined Type or Union), or element of an array. VARPTR returns a pointer (32-bit address in memory) where the variable data is stored.

VARPTR may also be used to locate an array descriptor, as well as the array data itself. To find the address of an array descriptor, use the array name with empty parentheses: VARPTR(x( )).

When you use VARPTR to get the address of a dynamic (variable length) string, keep in mind that the value being returned is the address of the string *handle*, not the actual *data* in the string. This can be useful for manipulating a dynamic string array using indexed-pointers, For example:

```
DIM A$(100), b$, pA AS STRING PTR, x&
' Assume A$() is filled here
pA = VARPTR(a$(0)) ' 1st element handle
FOR X& = 0 TO 100
  B$ = B$ + @pA[x&] + ","
NEXT x&
```

You can use STRPTR to find the address of the string's data. When used with pointers, VARPTR returns the address of the pointer itself.

Restrictions VARPTR cannot be used on Register variables, because Register variables are stored in internal processor registers rather than application memory. VARPTR can be used on UDT and Union variables, but not the UDT definition name. For example:

```
TYPE MyType
   ABC AS LONG
END TYPE
' more code here
DIM x AS MyTYPE, y&
y& = VARPTR(x)      ' This is legal
y& = VARPTR(MyType) ' This is not
```

See also CODEPTR, PEEK, Pointers, POKE, STRPTR

Example

```
DIM x AS INTEGER PTR, a%, b%
a% = 55
x = VARPTR(A%)
b% = @x
CALL DisplayResult("b% contains " + FORMAT$(b%))
```

Result

```
b% contains 55
```

VERIFY function

VERIFY function

Purpose Determine whether each character of a is present in another string.

Syntax ***x*** **= VERIFY([*start&*,] *MainString*, *MatchString*)**

Remarks VERIFY returns zero if each character in *MainString* is present in *MatchString*. If not, it returns the position of the first non-matching character in *MainString*.

This function is very useful for determining if a string contains only digits, for example.

VERIFY is case-sensitive, so capitalization matters.

Restrictions If *start&* evaluates to a position outside of the string on either side, or if *start&* is zero, VERIFY returns zero.

See also INSTR, LCASE$, LTRIM$, MID$, REMOVE$, REPLACE, RIGHT$, RTRIM$, TALLY, TRIM$, UCASE$

Example

```
' returns 4 since "." is not in "0123456789"
x& = VERIFY("123.65,22.5", "0123456789")
```

```
' returns 7 since 5 starts it past the first non-digit ("." at position 4)
x& = VERIFY(5,"123.65,22.5", "0123456789")
```

WHILE/WEND statements

WHILE/WEND statements

Purpose

Define a block of program statements that are executed repeatedly for as long as certain conditions are met.

Syntax

```
WHILE integer_expression
  [statements]
  [EXIT LOOP]
  [statements]
WEND
```

Remarks

If *integer_expression* is TRUE (it evaluates to a non-zero value), all of the statements between the WHILE and the terminating WEND are executed. PowerBASIC then jumps back to the WHILE statement and repeats the test. If it is still TRUE, PowerBASIC executes the enclosed statements again. This process is repeated until the test expression evaluates to zero, or an EXIT statement is encountered. In either case, execution passes to the statement following WEND.

If *integer_expression* evaluates to FALSE (zero) on the first pass, none of the statements in the loop are executed.

Loops built with WHILE/WEND statements can be nested (enclosed within each other). Each WEND matches the most recent unmatched WHILE.

One use of a WHILE/WEND loop is to input data from a file until the end of the file is reached:

```
i& = 0
WHILE ISFALSE EOF(1)
  INCR i&
  LINE INPUT #1, FileTxt$(i&)
WEND
```

Although the compiler does not care, it's a good idea to indent the statements between WHILE and WEND, to clarify the structure of the loop you have constructed.

Note that the following code creates in infinite loop:

```
WHILE -1
  [statements]
WEND
```

To exit a WHILE/WEND loop prematurely, use the EXIT LOOP statement.

PowerBASIC's DO/LOOP construct offers a more flexible way to build conditional loops.

Also see the discussion on the IF statement for notes on PowerBASIC's Short-circuit evaluation and its possible side effects.

WINDOW GET HANDLE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

WINDOW GET statement IMPROVED

Purpose Manipulate a Window in the program, which may include setting or retrieving data. The target window may be of any class, including a

or Dialog.

Syntax

```
WINDOW GET HANDLE hWin, ID& TO DataVar&
WINDOW GET ID hWin TO DataVar&
WINDOW GET PARENT hWin TO DataVar&
WINDOW GET STYLE hWin TO DataVar&
WINDOW GET STYLEX hWin TO DataVar&
WINDOW GET USER hWin TO DataVar&
```

hWin Handle of the Window to be used.

DataVar& A long integer variable to which result data is assigned.

Remarks The WINDOW statement may be used with any type of window in your program, including a Control or Dialog. Generally speaking, the window to be manipulated or tested is identified by its handle (*hWin*), which is often obtained at the time it is created. However, since a control is usually accessed by a "Parent / ID" combination, you must use WINDOW GET HANDLE or CONTROL HANDLE to retrieve its handle for this purpose. If the operation fails, the value zero (0) is assigned to the result variable.

WINDOW GET HANDLE *hWin, ID&* TO *DataVar&*

This statement retrieves the handle of a Window, translating from the parent handle and the specific integral control ID given at the time it was created. *hWin* is the handle of the parent, *ID&* is the control ID, and *DataVar&* represents the variable which receives the desired window handle.

WINDOW GET ID *hWin* To *DataVar&*

The integral ID of the window *hWin* is retrieved and assigned to the variable designated by *DataVar&*. Generally, only a CONTROL will have an ID, so windows of other classes will normally return the value zero.

WINDOW GET PARENT *hWin* To *DataVar&*

The handle of the parent is retrieved and assigned to the variable designated by *DataVar&*.

WINDOW GET STYLE hWin TO DataVar&

The window style value of the window specified by the handle *hWin* is retrieved and assigned to the variable designated by *DataVar&*.

WINDOW GET STYLEX *hWin* TO *DataVar&*

The extended window style value of the window specified by the handle *hWin* is retrieved and assigned to the variable designated by *DataVar&*.

WINDOW GET USER *hWin* TO *DataVar&*

The 32-bit user data value associated with the window specified by the handle *hWin* is retrieved and assigned to the variable designated by *DataVar&*. This particular user data value is associated with every window in your program, and is maintained by the Windows operating system. It is separate and apart from user data maintained by DDT for each dialog and control created with DDT.

Example

WINDOW SET statement New!

Purpose Manipulate a Window in the program, which may include setting or retrieving data. The target window may be of any class, including a

or Dialog.

Syntax

```
WINDOW SET ID hWin, NewVal& TO OldValVar&
WINDOW SET STYLE hWin, NewVal& TO OldValVar&
WINDOW SET STYLEX hWin, NewVal& TO OldValVar&
WINDOW SET USER hWin, NewVal& TO OldValVar&
```

hWin Handle of the Window to be used.

OldValVar& A long integer variable to which the old value of the item is assigned.

Remarks The WINDOW SET statement may be used with any type of window in your program, including a Control or Dialog. However, you must use care due to possible side effects. Generally speaking, the window to be manipulated is identified by its handle (*hWin*), which is often obtained at the time it is created. However, since a control is usually accessed by a "Parent / ID" combination, you must use WINDOW GET HANDLE or CONTROL HANDLE to retrieve its handle for this purpose.

<u>WINDOW SET ID *hWin*, *NewVal&* To *OldValVar&*</u>

The integral ID of the window *hWin* is changed to *NewVal&*. The prior ID value is assigned to the variable designated by *OldValVar&*. If the operation fails, the value zero (0) is assigned to *OldValVar&*. As a general rule, you should not change the ID of a Window, Dialog, or Control created with DDT as it will cause unpredictable results.

<u>WINDOW SET STYLE *hWin*, *NewVal&* TO *OldValVar&*</u>

The window style value of the window *hWin* is changed to *NewVal&*. The prior style value is assigned to the variable designated by *OldValVar&*. If the operation fails, the value zero (0) is assigned to *OldValVar&*.

<u>WINDOW SET STYLEX *hWin*, *NewVal&* TO *OldValVar&*</u>

The extended window style value of the window *hWin* is changed to *NewVal&*. The prior extended style value is assigned to the variable designated by *OldValVar&*. If the operation fails, the value zero (0) is assigned to *OldValVar&*.

WINDOW SET USER *hWin, NewVal&* TO *OldValVar&*

The 32-bit user data value associated with the window specified by the handle *hWin* is changed to *NewVal&*. The prior user data value is assigned to the variable designated by *OldValVar&*. This particular user data value is associated with every window in your program, and is maintained by the Windows operating system. It is separate and apart from user data maintained by DDT for each dialog and control created with DDT. If the operation fails, the value zero (0) is assigned to *OldValVar&*. However, this is not a certain indication of failure, since the prior user value might have been zero.

WINMAIN function

WINMAIN function

Purpose WINMAIN (or its synonym MAIN) is a user-defined function called by Windows to begin execution of an application.

Syntax

```
FUNCTION {WINMAIN | MAIN} ( _
    BYVAL  hInstance    AS DWORD, _
    BYVAL  hPrevInst    AS DWORD, _
    BYVAL  lpszCmdLine  AS WSTRINGZ PTR, _
    BYVAL  nCmdShow     AS LONG ) AS LONG
```

Remarks The WINMAIN function is called by Windows when an executable application first loads and begins to run. It is often referred to as the "entry point" for the application. When the execution of WINMAIN is completed, the application is deemed to be finished, and Windows releases the application memory back to the heap. WINMAIN receives the following parameters:

hInstance The executable's (EXE) *instance handle*. Each instance of a Windows application has a unique handle. It is used as a parameter to a number of Windows API functions which may need to distinguish between multiple instances of an application.

hPrevInst Not used by 32-bit Windows. It is present merely for compatibility with existing 16-bit code, and always returns zero in 32-bit applications.

lpszCmdLine A pointer to an nul-terminated string that contains a command-line. Note that the string passed in *lpszCmdLine* is not the same as the string returned by the *GetCommandLine* API call. The string in *lpszCmdLine* contains the command-line arguments only (like COMMAND$), but *GetCommandLine* returns the program name (including path) followed by the arguments.

nCmdShow Specifies how to display the application's main window. For example, the calling application can specify %SW_NORMAL or %SW_MINIMIZE, etc. It is up to the programmer to honor this parameter, and to do so is recommended.

Return

The return value assigned to WINMAIN is optional, but by convention, the return value is derived from the *wParam&* parameter of a %WM_QUIT message.

Typically, a GUI-based application uses the WINMAIN function to create the initial GUI application window, and then enters a message loop. This loop should terminate when a %WM_QUIT message is received, and the *wParam&* parameter of that message should be passed on as the return value for WINMAIN. If WINMAIN terminates before entering the message loop, WINMAIN should return zero.

Console applications may use the return value to set an error level that can be passed back to the calling application, in the range 0 to 255 inclusive. Batch files may act on the result through the IF [NOT] ERRORLEVEL batch command.

If the parameters passed to WINMAIN are not required by the application itself, the PBMAIN function may be used in place of WINMAIN.

Restrictions

Pointers may not be passed BYREF, so the *lpszCmdLine* parameter of WINMAIN must be declared to be passed BYVAL.

See also

PBMAIN

Example

```
#COMPILE EXE
FUNCTION WINMAIN(BYVAL hInst???, BYVAL hPrevInst???, BYVAL pCmdLine AS
WSTRINGZ PTR, BYVAL nCmdShow&) AS LONG
  ' more code here
  FUNCTION = 1
END FUNCTION
```

WRAP$ function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

WRAP$ function New!

Purpose

Add paired characters to the beginning and end of a

.

Syntax

***s$* = WRAP$(*StringExpression*, *LeftChar$*, *RightChar$*)**

Remarks

The WRAP$ function prepends LeftChar$ to the StringExpression, then appends RightChar$, and returns the total result. For example:

```
WRAP$("MyWord", "<", ">")  returns  "<MyWord>"
```

It is particularly useful for enclosing text with parenthesess, quotes, brackets, etc.

See also

BUILD$, STRINGBUILDER, STRINSERT$, UNWRAP$

WRITE# statement

WRITE# statement

Purpose Output data to a sequential file in a delimited format.

Syntax

```
WRITE #filenum&
WRITE #filenum&, [expression [{;|,} expression] ...] [;|,]
```

filenum& The file number used when the file or device was opened.

expression A

or a string expression representing the data to be written to the file or device.

Remarks WRITE# is similar to PRINT#, except WRITE# inserts a comma in the output file between each expression. It encloses

data within quotation marks, and adds no leading or trailing spaces around numeric values.

WRITE# is the preferred method of writing data to a sequential file, since it formats the output to be readable by the INPUT# statement. In other words, INPUT# respects the delimiter characters that separate items in a line of text, as created by WRITE#.

WRITE# with a file number and a comma but no expressions, outputs a carriage return to the file.

To read a delimited file without regard to the delimiter characters, use the LINE INPUT# statement.

Restrictions For best results, strings should not contain quotation marks, as these may interfere with the expected output format.

Each expression in the WRITE# statement must be separated from other expressions by a comma or semicolon. If you include a trailing comma or semicolon, the final carriage return / line feed is suppressed and replaced with a comma delimiter. This allows you to append data to the sequential record by executing another WRITE statement.

See also GET, GET$, GET$$, INPUT#, LINE INPUT#, OPEN, PRINT#, PUT, PUT$, PUT$$, SETEOF

Example

```
' Open a sequential output file and write to it
OPEN "FILE.TXT" FOR OUTPUT AS #1
WRITE #1, "TEST"
z& = -12345&
info1$ = "Do not covet"
info2$ = "thy neighbors ox"
WRITE #1, z&, info1$, info2$
WRITE #1, "TEST"
CLOSE #1
```

Result

```
"TEST"
-12345,"Do not covet","thy neighbors ox"
"TEST"
```

XOR operator

XOR operator

Purpose The XOR operator works as both a logical and a bitwise arithmetic operator.

Syntax *p* XOR *q*

Remarks

XOR as a logical operator

XOR returns FALSE (zero) if *and only if* both its operands have the same value. Here is XOR's truth table:

Truth table

x	y	x XOR y
T	T	F
T	F	T

F	T	T
F	F	F

Using XOR as a bitwise arithmetic operator

An XOR mask complements (reverses) selected bits of an

value, without affecting the other bits of that value. For example, to complement the two most-significant bits in &H9700, use XOR with a mask of &HC000; that is, all zeros except for the positions to be complemented:

```
        1001 0111 0000 0000 = &H9700
XOR     1100 0000 0000 0000 = &HC000 (the mask)
        0101 0111 0000 0000 = &H5700 (result)
MSB                                LSB (bit 0)
```

See also Arithmetic Operators, AND, EQV, IMP, NOT, OR

XPRINT Code Group

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT Code Group

Purpose

The

Code Group offers statements and functions which draw text and graphics on a Host Printer Page. In addition, it provides a wide variety of support to manage and interact with these items.

Syntax

```
XPRINT DirectorWord [params]
XPRINT DirectorWord [params] TO ReturnVariable(s)
```

```
Function Form:
ReturnVariable  = XPRINT(DirectorWord [,params] )
ReturnVariable$ = XPRINT$(DirectorWord [,params] )
```

Remarks

Some of the functionality of the XPRINT group was available in prior versions of PowerBASIC, but it has now been expanded. Some XPRINT Procedures (namely those which return a single value) may be used in two forms, a statement with a TO clause, or a function which may be used as a term in an expression:

```
XPRINT GET LINES TO LineCountVar&
LineCountVar& = XPRINT(LINES)
```

The two examples above are functionally identical. The choice is simply a matter of your personal preference. If you use the second form (as a function which returns a value), it can be a term in any expression of any complexity. When a function form is available, it is labeled with the prefix "Function Form".

Some XPRINT procedures return two or more values. As it is not possible to simultaneously inject multiple terms into a valid expression, the function option is not available for them.

PIXELS and POINTS

For the purposes of this discussion on XPRINT, the terms PIXELS and POINTS are considered to be synonyms. They may be used interchangeably.

XPRINT STREAM

The XPRINT Stream is the connection between XPRINT code and a host printer page. The XPrint Stream is created when you attach a particular printer with XPRINT ATTACH. From that moment forward, all XPrint code acts on that selected printer. This continues until such time as you end your print job with XPRINT CLOSE.

PAGE UNITS

PAGE UNITS are used to measure the size of a graphical item, or to define a particular position on an XPrint page. You can define page units to be points or scaled units of your choice.

Initially, each XPrint session begins with Page Units set to points. You can change this to scaled world coordinates of your choice with XPRINT SCALE.

By default, the upper left corner of a printer page is considered to be the X,Y position 0,0 and grows larger to the right or downward. The X axis is horizontal, while the Y axis is vertical. Whenever an X,Y position is given, the X value is stated first.

XPRINT POSITION (POS)

Each time you draw text or graphics, it is displayed at the current XPrint position (POS). Upon completion, the POS is updated to the last point referenced. You can draw a relative distance from the POS (using a STEP option), or set an entirely new position with XPRINT SET POS.

TEXT CELL (ROW/COLUMN POSITION)

For ease of programming, a few procedures specify text position by row and column. In this case, the position is measured in text cells, which is the space occupied by one character. This works well with fixed width fonts, which is recommended. If a variable width font is chosen, PowerBASIC must use the average character size for these calculations, which can give imprecise results.

For compatibility with most current and prior versions of BASIC (PowerBASIC included), code which references text rows and columns names the vertical term first (ROWS, COLUMNS). Rows and columns are always numbered from one upward.

See also Printing, Printing Commands

XPRINT(CANVAS.X) function

XPRINT GET CANVAS statement New!

Purpose Retrieves the writable size of the attached host printer.

Syntax

```
XPRINT GET CANVAS TO WidthVar!, HeightVar!

Function Form:
WidthVar!  = XPRINT(CANVAS.X)
HeightVar! = XPRINT(CANVAS.Y)
```

Remarks XPRINT GET CANVAS retrieves the logical size of the client area (printable area) for the attached host printer. This is the size of the page, minus the unprintable margins, without any reductions for a CLIP area. The size is specified in Page Units, so it could return scaled values if they were applied with XPRINT SCALE. This is very similar to XPRINT GET CLIENT, with the single exception that scaled values (set by XPRINT SCALE) are returned if they have been utilized. If executed without a host printer attached, error 57 is generated.

See also XPRINT GET CLIENT, XPRINT GET CLIP, XPRINT GET SIZE, XPRINT GET SCALE, XPRINT SCALE

XPRINT(CANVAS.Y) function

XPRINT GET CANVAS statement New!

Purpose Retrieves the writable size of the attached host printer.

Syntax

```
XPRINT GET CANVAS TO WidthVar!, HeightVar!

Function Form:
WidthVar!  = XPRINT(CANVAS.X)
HeightVar! = XPRINT(CANVAS.Y)
```

Remarks XPRINT GET CANVAS retrieves the logical size of the client area (printable area) for the attached host printer. This is the size of the page, minus the unprintable margins, without any reductions for a CLIP area. The size is specified in Page Units, so it could return scaled values if they were applied with XPRINT SCALE. This is very similar to XPRINT GET CLIENT, with the single exception that scaled values (set by XPRINT SCALE) are returned if they have been utilized. If executed without a host printer attached, error 57 is generated.

See also XPRINT GET CLIENT, XPRINT GET CLIP, XPRINT GET SIZE, XPRINT GET SCALE, XPRINT SCALE

XPRINT(Cell.Size.X) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT CELL SIZE statement New!

Purpose Retrieve the character cell size including external leading.

Syntax

```
XPRINT CELL SIZE TO WidthVar, HeightVar!

Function Form:
WidthVar!  = XPRINT(Cell.Size.X)
HeightVar! = XPRINT(Cell.Size.Y)
```

Remarks XPRINT CELL SIZE retrieves the size of one character cell, for the current font, on the attached printer. The returned cell size is specified in PAGE UNITS, and allows you to calculate the number of text lines which will fit in a particular space. The height value is the size of the displayed character, including external leading (if any) for this particular font.

If the font is a fixed-width font, like Courier New or Lucida Console,the sizes returned are as exact as possible, given the fractional rounding approximations necessary for some scaled units. If the font is proportional, like Arial or Times New Roman, the width will be the average size for the entire font.

External leading is the vertical distance from the bottom of one character to the top of the character below it. This value is specified by the font in use. It may vary from zero to a larger value, depending upon the font and point size. To retrieve the exact height of characters without external leading, use XPRINT CHR SIZE.

See also XPRINT CELL, XPRINT CHR SIZE, XPRINT SET FONT, XPRINT TEXT SIZE

XPRINT(Cell.Size.Y) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT CELL SIZE statement New!

Purpose Retrieve the character cell size including external leading.

Syntax

```
XPRINT CELL SIZE TO WidthVar, HeightVar!

Function Form:
WidthVar!  = XPRINT(Cell.Size.X)
HeightVar! = XPRINT(Cell.Size.Y)
```

Remarks XPRINT CELL SIZE retrieves the size of one character cell, for the current font, on the attached printer. The returned cell size is specified in PAGE UNITS, and allows you to calculate the number of text lines which will fit in a particular space. The height value is the size of the displayed character, including external leading (if any) for this particular font.

If the font is a fixed-width font, like Courier New or Lucida Console,the sizes returned are as exact as possible, given the fractional rounding approximations necessary for some scaled units. If the font is proportional, like Arial or Times New Roman, the width will be the average size for the entire font.

External leading is the vertical distance from the bottom of one character to the top of the character below it. This value is specified by the font in use. It may vary from zero to a larger value, depending upon the font and point size. To retrieve the exact height of characters without external leading, use XPRINT CHR SIZE.

See also XPRINT CELL, XPRINT CHR SIZE, XPRINT SET FONT, XPRINT TEXT SIZE

XPRINT(Chr.Size.X) function

XPRINT CHR SIZE statement IMPROVED

Purpose Retrieve the character size for the current font on a host printer page.

Syntax

```
XPRINT CHR SIZE TO WidthVar!, HeightVar!

Function Form:
WidthVar!  = XPRINT(Chr.Size.X)
HeightVar! = XPRINT(Chr.Size.Y)
```

Remarks The character size is specified in the same terms (pixels or scaled units) as originally stated. The height value retrieved is the actual size of the printed character without including any external leading for this particular font.

If the font is a fixed-width font, like Courier New or Lucida Console, the sizes returned are as exact as possible, given the fractional rounding approximations possible when converting from pixels to other coordinates. If the font is proportional, like Arial or Times New Roman, the width will be the average size for the entire font.

External leading is the vertical distance from the bottom of one character to the top of the character below it. This value is specified by the font in use. It may vary from zero to a larger value, depending upon the font and point size. To retrieve the total row height including external leading, use XPRINT CELL SIZE.

See also XPRINT, XPRINT ATTACH, XPRINT CELL SIZE, XPRINT SET FONT, XPRINT TEXT SIZE

XPRINT(Chr.Size.Y) function

XPRINT CHR SIZE statement IMPROVED

Purpose Retrieve the character size for the current font on a host printer page.

Syntax

```
XPRINT CHR SIZE TO WidthVar!, HeightVar!
Function Form:
WidthVar!  = XPRINT(Chr.Size.X)
HeightVar! = XPRINT(Chr.Size.Y)
```

Remarks The character size is specified in the same terms (pixels or scaled units) as originally stated. The height value retrieved is the actual size of the printed character without including any external leading for this particular font.

If the font is a fixed-width font, like Courier New or Lucida Console, the sizes returned are as exact as possible, given the fractional rounding approximations possible when converting from pixels to other coordinates. If the font is proportional, like Arial or Times New Roman, the width will be the average size for the entire font.

External leading is the vertical distance from the bottom of one character to the top of the character below it. This value is specified by the font in use. It may vary from zero to a larger value, depending upon the font and point size. To retrieve the total row height including external leading, use XPRINT CELL SIZE.

See also XPRINT, XPRINT ATTACH, XPRINT CELL SIZE, XPRINT SET FONT, XPRINT TEXT SIZE

XPRINT(Client.X) function

XPRINT GET CLIENT statement IMPROVED

Purpose Retrieves the size of the client area (printable area) on the host printer page.

Syntax

```
XPRINT GET CLIENT To WidthVar!, HeightVar!
Function Form:
WidthVar!  = XPRINT(Client.X)
HeightVar! = XPRINT(Client.Y)
```

Remarks XPRINT GET CLIENT retrieves the physical size of the client area (printable area) for the attached host printer. The size is always specified in Pixels (points). This is very similar to XPRINT GET CANVAS, with the single exception that scaled values (set by XPRINT SCALE) are not utilized. If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET CANVAS, XPRINT GET CLIP, XPRINT GET MARGIN, XPRINT GET PPI, XPRINT GET SIZE

XPRINT(Client.Y) function

XPRINT GET CLIENT statement IMPROVED

Purpose Retrieves the size of the client area (printable area) on the host printer page.

Syntax

```
XPRINT GET CLIENT To WidthVar!, HeightVar!

Function Form:
WidthVar!  = XPRINT(Client.X)
HeightVar! = XPRINT(Client.Y)
```

Remarks XPRINT GET CLIENT retrieves the physical size of the client area (printable area) for the attached host printer. The size is always specified in Pixels (points). This is very similar to XPRINT GET CANVAS, with the single exception that scaled values (set by XPRINT SCALE) are not utilized. If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET CANVAS, XPRINT GET CLIP, XPRINT GET MARGIN, XPRINT GET PPI, XPRINT GET SIZE

XPRINT(Clip.X) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET CLIP statement New!

Purpose Retrieves the size of the clip area on the selected printer.

Syntax

```
XPRINT GET CLIP TO WidthVar!, HeightVar!

Function Form:
WidthVar!  = XPRINT(Clip.X)
HeightVar! = XPRINT(Clip.Y)
```

Remarks The clip area of the printer is that space where print operations can be written. That is, the clip area is that portion of the client area which is not protected (clipped) by the XPRINT SET CLIP statement.

XPRINT GET CLIP retrieves the size of the clip area, and assigns these values to the variables specified by *WidthVar!* and *HeightVar!*. The size is specified in PAGE UNITS (pixels/points or scaled units). If no printer is selected, the values 0,0 are returned.

See also XPRINT GET CANVAS, XPRINT GET CLIENT, XPRINT SET CLIP

XPRINT(Clip.Y) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET CLIP statement New!

Purpose Retrieves the size of the clip area on the selected printer.

Syntax

```
XPRINT GET CLIP TO WidthVar!, HeightVar!

Function Form:
WidthVar!  = XPRINT(Clip.X)
HeightVar! = XPRINT(Clip.Y)
```

Remarks The clip area of the printer is that space where print operations can be written. That is, the clip area is that portion of the client area which is not protected (clipped) by the XPRINT SET CLIP statement.

XPRINT GET CLIP retrieves the size of the clip area, and assigns these values to the variables specified by *WidthVar!* and *HeightVar!*. The size is specified in PAGE UNITS (pixels/points or scaled units). If no printer is selected, the values 0,0 are returned.

See also XPRINT GET CANVAS, XPRINT GET CLIENT, XPRINT SET CLIP

XPRINT(COL) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT CELL statement New!

Purpose Sets or retrieves the next print position (LPR - Last Point Referenced), based upon the row and column position of a text cell.

Syntax

```
XPRINT CELL = RowValue&, ColValue&
XPRINT CELL TO RowVar&, ColVar&
XPRINT COL TO ColVar&
XPRINT ROW TO RowVar&

Function Form:
ColVar& = XPRINT(COL)
RowVar& = XPRINT(ROW)
```

Remarks XPRINT CELL is used to set or retrieve the print position, based upon the row and column position of a Text Cell. That is the row and column position where the next printed text will be displayed. *RowValue&* specifies the horizontal screen row (starting at 1) at which to position the cursor. *ColValue&* specifies the vertical screen column (starting at 1) at which to position the cursor. Since row and column numbers start at one (1), the upper left corner of the page is considered to be cell 1,1.

The first form of XPRINT CELL moves the print position to the desired row and column. If a value given is zero (0), that parameter is ignored and that position is not changed. The second form of XPRINT CELL retrieves the current print position, and assigns the values to the variables specified by *RowVar&* and *ColVar&*.

The remaining forms allow you to retrieve just a single value, either row or column, and are supported in both statement and function form.

See also XPRINT CELL SIZE, XPRINT SET FONT, XPRINT SET WORDWRAP, XPRINT SET WRAP, XPRINT SPLIT

XPRINT(COLLATE) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET COLLATE statement IMPROVED

Purpose Retrieves the XPRINT collate status.

Syntax

```
XPRINT GET COLLATE TO CollateVar&
```

Function Form:

```
CollateVar& = XPRINT(COLLATE)
```

Remarks XPRINT allows you to set the collate status, if the printer driver supports both multiple copies and collate capability. XPRINT GET COLLATE retrieves the collate status, assigning the value to the long integer variable specified by *CollateVar&*. The following equates are predefined in the compiler to symbolically represent the possible collate status:

```
%DMCOLLATE_FALSE       = 0
%DMCOLLATE_TRUE        = 1
```

If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT SET COLLATE

XPRINT(COLORMODE) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET COLORMODE statement IMPROVED

Purpose Retrieves the XPRINT colormode status.

Syntax

```
XPRINT GET COLORMODE TO ColorVar&
```

Function Form:

ColorVar& **= XPRINT(COLORMODE)**

Remarks XPRINT allows you to set the color or monochrome print mode if the printer driver supports it. XPRINT GET COLORMODE retrieves the colormode status, assigning the value to the long integer variable specified by *ColorVar&*. The value zero may be returned if colormode is not supported by the printer driver. The following equates are predefined in the compiler to symbolically represent the possible status:

```
%DMCOLOR_MONOCHROME    = 1
%DMCOLOR_COLOR         = 2
```

If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT SET COLORMODE

XPRINT(COPIES) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET COPIES statement IMPROVED

Purpose Retrieves the XPRINT copy count.

Syntax **XPRINT GET COPIES TO** ***CopyVar&***

Function Form:

CopyVar& **= XPRINT(COPIES)**

Remarks XPRINT allows you to set the number of copies to be automatically printed, if it is supported by the printer driver. XPRINT GET COPIES retrieves the copy count, assigning the value to the long integer variable specified by *CopyVar&*. The default value is one (1). If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT SET COPIES

XPRINT(DC) function

XPRINT GET DC statement IMPROVED

Purpose Retrieve the handle of the device context (DC) for the host printer page.

Syntax **XPRINT GET DC TO** ***hDC***

Function Form:
hDC **= XPRINT(DC)**

Remarks If no host printer is currently attached, zero is returned. The DC handle may be used with various Windows API functions to perform specialized operations on the host printer page.

See also XPRINT ATTACH

XPRINT(DUPLEX) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET DUPLEX statement IMPROVED

Purpose Retrieve the XPRINT duplex status.

Syntax **XPRINT GET DUPLEX TO *DuplexVar&***

Function Form:
***DuplexVar&* = XPRINT(DUPLEX)**

Remarks XPRINT allows you to get/set the duplex status, if the printer supports printing on both sides of a page. XPRINT GET DUPLEX retrieves the duplex status, assigning the value to the long integer variable specified by *DuplexVar&*. The following equates are predefined in the compiler to symbolically represent the possible duplex status:

```
%DMDUP_SIMPLEX        = 1    (single sided printing)
%DMDUP_VERTICAL       = 2    (page flipped on the vertical edge)
%DMDUP_HORIZONTAL     = 3    (page flipped on the horizontal edge)
```

If the printer does not support duplex printing, the value zero (0) is returned. If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT SET DUPLEX

XPRINT(LINES) function

XPRINT GET LINES statement IMPROVED

Purpose Retrieve the number of lines that can be printed.

Syntax **XPRINT GET LINES To *LineVar&***

Function Form:
***LineVar&* = XPRINT(LINES)**

Remarks XPRINT GET LINES retrieves the number of lines of text which can be printed on the host printer page, given the current selected font. Since

statements do not generate an automatic formfeed when text is printed on the last line, this statement can be used to determine when your program should execute an XPRINT FORMFEED to move to the next printed page on a host printer. If executed without a host printer attached, error 57 is generated.

See also XPRINT, XPRINT ATTACH, XPRINT SET FONT, XPRINT FORMFEED

XPRINT(MIX) function

XPRINT GET MIX statement IMPROVED

Purpose Retrieve the color mix mode for a host printer page.

Syntax **XPRINT GET MIX To *MixVar&***

Function Form:

```
MixVar& = XPRINT(MIX)
```

Remarks Prior to any

operations, a host printer must first be selected with XPRINT ATTACH. There are 16 mix modes available to use for mixing the drawing color with the color that already exists at the drawing location. The mix mode equates are predefined in PowerBASIC. If executed without a host printer attached, error 57 is generated.

%MIX_BLACKNESS	Pixel is always 0 (black).
%MIX_NOTMERGESRC	Pixel is the inverse of the MergeSrc color.
%MIX_MASKNOTSRC	Pixel is a combination of the colors common to both the pixel and the inverse of the source.
%MIX_NOTCOPYSRC	Pixel is the inverse of the pen color.
%MIX_MASKSRCNOT	Pixel is a combination of the colors common to both the source and the inverse of the pixel.
%MIX_NOT	Pixel is the inverse of the pixel color.
%MIX_XORSRC	Pixel is a combination of the colors in the source and in the pixel, but not in both.
%MIX_NOTMASKSRC	Pixel is the inverse of the MaskSrc color.
%MIX_MASKSRC	Pixel is a combination of the colors common to both the source and the pixel.
%MIX_NOTXORSRC	Pixel is the inverse of the XorSrc color.
%MIX_NOP	Pixel remains unchanged.
%MIX_MERGENOTSRC	Pixel is a combination of the source color and the inverse of the pixel color.
%MIX_COPYSRC	Pixel is the source color (default).
%MIX_MERGESRCNOT	Pixel is a combination of the source color and the inverse of the pixel color.
%MIX_MERGESRC	Pixel is a combination of the source color and the pixel color.
%MIX_WHITENESS	Pixel is always 1 (white).

See also XPRINT ATTACH, XPRINT SET MIX

XPRINT(ORIENTATION) function

XPRINT GET ORIENTATION statement IMPROVED

Purpose Retrieve the paper orientation for a host printer page.

Syntax

```
XPRINT GET ORIENTATION To OrentVar&
Function Form:
OrentVar& = XPRINT(ORIENTATION)
```

Remarks XPRINT GET ORIENTATION retrieves the orientation of the paper in the host printer, assigning the value to the long integer variable specified by *OrentVar&*. The value 1 indicates portrait mode, while 2 indicates landscape mode. If the printer does not support paper orientation, 0 is returned. If a host printer is not attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT SET ORIENTATION

XPRINT(OVERLAP) function

XPRINT GET OVERLAP statement New!

Purpose Retrieves the status of XPrint Overlap Mode.

Syntax

```
XPRINT GET OVERLAP To OverlapVar&
Function Form:
```

OverlapVar& **= XPRINT(OVERLAP)**

Remarks XPRINT GET OVERLAP retrieves the status of overlap mode and assigns it to the variable specified by *OverlapVar&*. If Overlap Mode is enabled, the value true (non-zero) is assigned. If it's disabled, the value false (zero) is assigned instead. The value returned reflects the status of the host printer which is currently attached to the XPrint stream.

With Overlap Mode, you can control how PowerBASIC treats XPrint operations which involve a bounding rectangle (RECT structure) in their definition. Windows maintains unique conventions for a RECT. The bottom and right coordinates of a RECT are exclusive. In other words, the pixels at the bottom and right edges lie immediately outside the rectangle. They are ignored. For example:

```
XPRINT BOX (0,0) - (50,50)
```

In this case, a box is drawn from 0,0 to 49,49. The final pixels at the bottom and right edge are simply not drawn. However, if Overlap Mode is enabled with XPRINT SET OVERLAP, the box is drawn from 0,0 to 50,50.

The Overlap Mode affects all XPRINT functions which take a bounding rectangle as a parameter. This includes XPRINT SCALE, XPRINT BOX, XPRINT ELLIPSE, XPRINT LINE, XPRINT POLYLINE, etc.

See also XPRINT SET OVERLAP

XPRINT(PAPER) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET PAPER statement IMPROVED

Purpose Retrieves the current paper size/type.

Syntax **XPRINT GET PAPER TO *PaperVar&***

Function Form:
PaperVar& **= XPRINT(PAPER)**

Remarks XPRINT GET PAPER retrieves the paper style for which the host printer is currently configured. The paper style is identified by an

value which is assigned to the long integer variable specified by *PaperVar&*. The following equates are predefined in the compiler, and represent the most common paper styles:

```
%DMPAPER_LETTER    =  1      Letter    8.5   x 11    inches
%DMPAPER_TABLOID   =  3      Tabloid   11    x 17    inches
%DMPAPER_LEDGER    =  4      Ledger    17    x 11    inches
%DMPAPER_LEGAL     =  5      Legal     8.5   x 14    inches
%DMPAPER_STATEMENT =  6      Statement 5.5   x 8.5   inches
%DMPAPER_EXECUTIVE =  7      Executive 7.25  x 10.5  inches
%DMPAPER_A3        =  8      A3        297   x 420   mm
%DMPAPER_A4        =  9      A4        210   x 297   mm
%DMPAPER_A5        = 11      A5        148   x 210   mm
%DMPAPER_B4        = 12      B4        250   x 354   mm
%DMPAPER_B5        = 13      B5        182   x 257   mm
```

```
%DMPAPER_FOLIO      = 14      Folio     8.5   x 13    inches
%DMPAPER_QUARTO     = 15      Quarto    215   x 275   mm
%DMPAPER_10X14      = 16      10x14     10    x 14    inches
%DMPAPER_11X17      = 17      11x17     11    x 17    inches
%DMPAPER_NOTE       = 18      Note      8.5   x 11    inches
%DMPAPER_ENV_9      = 19      9 Envlp   3.875 x 8.875 inches
%DMPAPER_ENV_10     = 20      10 Envlp  4.125 x 9.5   inches
```

Other paper style codes may be defined by Windows or printer suppliers. You can use XPRINT GET PAPERS to obtain a list of all the paper styles supported by the attached host printer.

If the printer does not support paper style changes, the value zero is returned. If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET PAPERS, XPRINT SET PAPER

XPRINT(PIXEL...) function

XPRINT GET PIXEL statement IMPROVED

Purpose Retrieves the color of a pixel on a host printer page.

Syntax **XPRINT GET PIXEL [STEP] (x!, y!) TO *PixelVar&***

Function Form:
***PixelVar&* = XPRINT(PIXEL [STEP], *x!*, *y!*)**

Remarks Not all printer drivers support the ability to retrieve the color of a pixel. If this feature is not supported, or if the coordinates are outside the printer client area, an invalid color value of -1 is returned. If no host printer is attached, error 57 is generated.

See also Built In RGB Color Equates, XPRINT ATTACH, XPRINT COLOR, XPRINT SET PIXEL

XPRINT(POS.X) function

XPRINT GET POS statement IMPROVED

Purpose Retrieves the last point referenced (POS) by an statement.

Syntax **XPRINT GET POS TO *XVar!*, *YVar!***

Function Form:
***XVar!* = XPRINT(POS.X)**
***YVar!* = XPRINT(POS.Y)**

Remarks XPRINT GET POS allows you to retrieve the last point referenced (POS) by XPRINT statements. The coordinate points are specified in Page Units. If executed without a host printer attached, an error 57 is generated, and the values 0,0 are returned.

See also XPRINT ATTACH, XPRINT SET POS

XPRINT(POS.Y) function

XPRINT GET POS statement IMPROVED

Purpose Retrieves the last point referenced (POS) by an statement.

Syntax **XPRINT GET POS TO *XVar!*, *YVar!***

```
Function Form:
XVar! = XPRINT(POS.X)
YVar! = XPRINT(POS.Y)
```

Remarks XPRINT GET POS allows you to retrieve the last point referenced (POS) by XPRINT statements. The coordinate points are specified in Page Units. If executed without a host printer attached, an error 57 is generated, and the values 0,0 are returned.

See also XPRINT ATTACH, XPRINT SET POS

XPRINT(PPI.X) function

XPRINT GET PPI statement IMPROVED

Purpose Retrieves the resolution of the host printer page.

Syntax

```
XPRINT GET PPI TO XVar&, YVar&
Function Form:
XVar& = XPRINT(PPI.X)
YVar& = XPRINT(PPI.Y)
```

Remarks XPRINT GET PPI retrieves the resolution (points per inch) of the host printer page. The resolution is always specified in pixels, regardless of any XPRINT SCALE option. If executed without a host printer attached, error 57 is generated, and the values 0,0 are returned. This statement is particularly useful in drawing items such as rulers and graphs to a particular physical size. There are 25.4 millimeters per inch, so just divide by 25.4 to convert from pixels per inch to pixels per millimeter.

See also XPRINT ATTACH, XPRINT GET CLIENT, XPRINT GET MARGIN, XPRINT GET SIZE

XPRINT(PPI.Y) function

XPRINT GET PPI statement IMPROVED

Purpose Retrieves the resolution of the host printer page.

Syntax

```
XPRINT GET PPI TO XVar&, YVar&
Function Form:
XVar& = XPRINT(PPI.X)
YVar& = XPRINT(PPI.Y)
```

Remarks XPRINT GET PPI retrieves the resolution (points per inch) of the host printer page. The resolution is always specified in pixels, regardless of any XPRINT SCALE option. If executed without a host printer attached, error 57 is generated, and the values 0,0 are returned. This statement is particularly useful in drawing items such as rulers and graphs to a particular physical size. There are 25.4 millimeters per inch, so just divide by 25.4 to convert from pixels per inch to pixels per millimeter.

See also XPRINT ATTACH, XPRINT GET CLIENT, XPRINT GET MARGIN, XPRINT GET SIZE

XPRINT(QUALITY) function

XPRINT GET QUALITY statement IMPROVED

Purpose Retrieves the print quality setting for the host printer.

Syntax

```
XPRINT GET QUALITY To QualVar&
Function Form:
QualVar& = XPRINT(QUALITY)
```

Remarks XPRINT GET QUALITY retrieves the print quality setting for the host printer. The value 1 is draft mode, 2 is low resolution, 3 is medium resolution, and 4 is high resolution. If the printer does not support print quality settings, 0 is returned. If no host printer is attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT SET QUALITY

XPRINT(ROW) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT CELL statement New!

Purpose Sets or retrieves the next print position (LPR - Last Point Referenced), based upon the row and column position of a text cell.

Syntax

```
XPRINT CELL = RowValue&, ColValue&
XPRINT CELL TO RowVar&, ColVar&
XPRINT COL TO ColVar&
XPRINT ROW TO RowVar&
```

```
Function Form:
ColVar& = XPRINT(COL)
RowVar& = XPRINT(ROW)
```

Remarks XPRINT CELL is used to set or retrieve the print position, based upon the row and column position of a Text Cell. That is the row and column position where the next printed text will be displayed. *RowValue&* specifies the horizontal screen row (starting at 1) at which to position the cursor. *ColValue&* specifies the vertical screen column (starting at 1) at which to position the cursor. Since row and column numbers start at one (1), the upper left corner of the page is considered to be cell 1,1.

The first form of XPRINT CELL moves the print position to the desired row and column. If a value given is zero (0), that parameter is ignored and that position is not changed. The second form of XPRINT CELL retrieves the current print position, and assigns the values to the variables specified by *RowVar&* and *ColVar&*.

The remaining forms allow you to retrieve just a single value, either row or column, and are supported in both statement and function form.

See also XPRINT CELL SIZE, XPRINT SET FONT, XPRINT SET WORDWRAP, XPRINT SET WRAP, XPRINT SPLIT

XPRINT(SELECTION) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET SELECTION statement New!

Purpose Retrieves the status of the SELECTION flag.

Syntax
```
XPRINT GET SELECTION TO SelectVar&

Function Form:
SelectVar& = XPRINT(SELECTION)
```

Remarks You may elect to limit a particular print job to just that part of the total which is selected/highlighted. If so, it is the programmer's responsibility to limit XPRINT output to just the selected region.

The selection flag can only be set by the user in the Print Dialog which is displayed when XPRINT ATTACH is executed with the CHOOSE option. It cannot be set under program control. This flag is maintained only to give the programmer information about the user's request. If you do not wish to honor this option, you should disable it in XPRINT ATTACH CHOOSE.

If XPRINT GET SELECTION is executed without a host printer attached, an error 57 is generated.

See also XPRINT ATTACH

XPRINT(SIZE.X) function

XPRINT GET SIZE statement IMPROVED

Purpose Retrieve the total size of the host printer page.

Syntax
```
XPRINT GET SIZE TO WidthVar&, HeightVar&

Function Form:
WidthVar&  = XPRINT(SIZE.X)
HeightVar& = XPRINT(SIZE.Y)
```

Remarks XPRINT GET SIZE allows you to retrieve the full size of the host printer page, including both the printable client area and any unprintable margins. The sizes are specified in pixels (points). If no host printer is attached, error 57 is generated, and the values 0,0 are returned.

See also XPRINT ATTACH, XPRINT GET CLIENT, XPRINT GET MARGIN, XPRINT GET MIX, XPRINT GET PPI

XPRINT(SIZE.Y) function

XPRINT GET SIZE statement IMPROVED

Purpose Retrieve the total size of the host printer page.

Syntax
```
XPRINT GET SIZE TO WidthVar&, HeightVar&

Function Form:
WidthVar&  = XPRINT(SIZE.X)
HeightVar& = XPRINT(SIZE.Y)
```

Remarks XPRINT GET SIZE allows you to retrieve the full size of the host printer page, including both the printable client area and any unprintable margins. The sizes are specified in pixels (points). If no host printer is attached, error 57 is generated, and the values 0,0 are returned.

See also XPRINT ATTACH, XPRINT GET CLIENT, XPRINT GET MARGIN, XPRINT GET MIX, XPRINT GET PPI

XPRINT(STRETCHMODE) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET STRETCHMODE statement New!

Purpose Retrieves the default bitmap stretching mode for the attached DC.

Syntax

```
XPRINT GET STRETCHMODE TO ModeVar&
```

Function Form:

```
ModeVar& = XPRINT(STRETCHMODE)
```

Remarks There are several operations in PowerBASIC which involve stretching or condensing images on bitmaps, most notably XPRINT STRETCH. As individual points must be added or removed, there is a good chance that the quality of the image will be degraded. However, if you describe the nature of the image by defining a StretchMode, you can substantially enhance the appearance.

The default StretchMode is maintained individually for each DC. You can retrieve the default mode with this statement, or set it with XPRINT SET STRETCHMODE. Of course, you can also override the default StretchMode when you execute one of the affected statements.

The 4 stretch mode equates are predefined in PowerBASIC.

%BLACKONWHITE	1	This is the default Windows stretch mode, and is most appropriate for monochrome bitmaps, or those with blocks of color. Performs a boolean OR of eliminated and existing pixels. It preserves black pixels at the expense of white pixels.
%WHITEONBLACK	2	Performs a boolean OR of eliminated and existing pixels. It preserves white pixels at the expense of black pixels.
%COLORONCOLOR	3	Deletes eliminated lines of pixels without trying to preserve their information.
%HALFTONE	4	This provides the highest quality for complex color bitmaps. The average color of the destination pixel block is kept approximately the same as the source pixel block.

See also XPRINT COPY, XPRINT RENDER, XPRINT STRETCH, XPRINT SET STRETCHMODE

XPRINT(TEXT.SIZE.X...) function

XPRINT TEXT SIZE statement IMPROVED

Purpose Calculate the size of text to be printed on a host printer.

Syntax **XPRINT TEXT SIZE *txt$* To *nWidth!*, *nHeight!***

Function Form:
***WidthVar!* = XPRINT(TEXT.SIZE.X, *txt$*)**
***HeightVar!* = XPRINT(TEXT.SIZE.Y, *txt$*)**

Remarks This statement calculates the total size of the printed text, based upon the current font for the host printer. The sizes returned are specified in Page Units.

This allows you to easily calculate the appropriate print position, particularly when using a proportional font. If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT CELL SIZE, XPRINT CHR SIZE, XPRINT SET FONT

Example

```
FUNCTION PBMAIN
  ' The following example draws the text both horizontally
  ' and vertically centered on the host printer page

  LOCAL x, y, w, h, w2, h2 AS LONG
  LOCAL sText AS STRING
  sText = "PowerBASIC"

  XPRINT ATTACH "Lexmark C750"
  XPRINT COLOR %BLUE, -2  ' blue text, clear background
  XPRINT FONT "Times New Roman", 18, 3  ' 18p, bold, italic

  XPRINT GET CLIENT TO w, h  ' get client size
  XPRINT TEXT SIZE sText TO w2, h2      ' get text size
  x = (w-w2) / 2                        ' centered x-pos
  y = (h-h2) / 2                        ' centered y-pos

  XPRINT SET POS (x, y)                 ' set position
  XPRINT sText                          ' draw the text
  XPRINT CLOSE
END FUNCTION
```

XPRINT(TEXT.SIZE.Y...) function

XPRINT TEXT SIZE statement IMPROVED

Purpose Calculate the size of text to be printed on a host printer.

Syntax **XPRINT TEXT SIZE *txt$* To *nWidth!*, *nHeight!***

Function Form:
***WidthVar!* = XPRINT(TEXT.SIZE.X, *txt$*)**
***HeightVar!* = XPRINT(TEXT.SIZE.Y, *txt$*)**

Remarks This statement calculates the total size of the printed text, based upon the current font for the host printer. The sizes returned are specified in Page Units.

This allows you to easily calculate the appropriate print position, particularly when using a proportional font. If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT CELL SIZE, XPRINT CHR SIZE, XPRINT SET FONT

Example

```
FUNCTION PBMAIN
  ' The following example draws the text both horizontally
  ' and vertically centered on the host printer page
```

```
  LOCAL x, y, w, h, w2, h2 AS LONG
  LOCAL sText AS STRING
  sText = "PowerBASIC"

  XPRINT ATTACH "Lexmark C750"
  XPRINT COLOR %BLUE, -2  ' blue text, clear background
  XPRINT FONT "Times New Roman", 18, 3  ' 18p, bold, italic

  XPRINT GET CLIENT TO w, h  ' get client size
  XPRINT TEXT SIZE sText TO w2, h2      ' get text size
  x = (w-w2) / 2                        ' centered x-pos
  y = (h-h2) / 2                        ' centered y-pos

  XPRINT SET POS (x, y)                 ' set position
  XPRINT sText                          ' draw the text
  XPRINT CLOSE
END FUNCTION
```

XPRINT(TRAY) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET TRAY statement IMPROVED

Purpose Retrieves the active printer tray.

Syntax `XPRINT GET TRAY TO` ***TrayVar&***

Function Form:
TrayVar& `= XPRINT(TRAY)`

Remarks XPRINT GET TRAY retrieves the paper tray which is active on the host printer. A descriptive value is assigned to the long integer variable specified by *TrayVar&*. The following equates are predefined in the compiler, and represent the most common paper trays:

```
%DMBIN_UPPER         = 1
%DMBIN_LOWER         = 2
%DMBIN_MIDDLE        = 3
%DMBIN_MANUAL        = 4
%DMBIN_ENVELOPE      = 5
%DMBIN_ENVMANUAL     = 6
%DMBIN_AUTO          = 7
%DMBIN_TRACTOR       = 8
%DMBIN_SMALLFMT      = 9
%DMBIN_LARGEFMT      = 10
%DMBIN_LARGECAPACITY = 11
%DMBIN_CASSETTE      = 14
%DMBIN_FORMSOURCE    = 15
```

Other tray codes may be defined by Windows or printer suppliers, so your program should be written to consider that possibility. You can use XPRINT GET TRAYS to obtain a list of all the paper trays supported by the attached host printer.

If the printer does not support the tray change requested, error 5 is generated. If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET TRAYS, XPRINT SET TRAY

XPRINT(WORDWRAP) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET WORDWRAP statement New!

Purpose Retrieves the status of XPRINT WordWrap Mode.

Syntax **XPRINT GET WORDWRAP TO *WrapVar&***

Function Form:
***WrapVar&* = XPRINT(WORDWRAP)**

Remarks XPRINT GET WORDWRAP retrieves the status of wordwrap mode and assigns it to the variable specified by *WrapVar&*. If WordWrap Mode is enabled, the value true (non-zero) is assigned. If it's disabled, the value false (zero) is assigned instead. The value returned reflects the status of the attached printer.

With WordWrap Mode, you can control how PowerBASIC prints text on an XPRINT page when it reaches the end of a line. Since XPRINT operates on a full page basis, the default is to ignore text which is printed past the end of the line. This can be modified under program control by using XPRINT SET WORDWRAP.

When WordWrap mode is enabled, it affects only XPRINT print operations. If XPRINT print attempts to display a word beyond the end of a row, the entire word is automatically wrapped to the first column of the next row.

See also XPRINT CELL, XPRINT GET WRAP, XPRINT SET WORDWRAP, XPRINT SET WRAP, XPRINT SPLIT

XPRINT(WRAP) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET WRAP statement New!

Purpose Retrieves the status of XPRINT Wrap Mode.

Syntax **XPRINT GET WRAP TO *WrapVar&***

Function Form:
***WrapVar&* = XPRINT(WRAP)**

Remarks XPRINT GET WRAP retrieves the status of wrap mode and assigns it to the variable specified by *WrapVar&*. If Wrap Mode is enabled, the value true (non-zero) is assigned. If it's disabled, the value false (zero) is assigned instead. The value returned reflects the status of the attached printer.

With Wrap Mode, you can control how PowerBASIC prints text on an XPRINT page when it reaches the end of a line. Since XPRINT operates on a full page basis, the default is to ignore text which is printed past the end of the line. This can be modified under program control by using XPRINT SET WRAP.

When Wrap Mode is enabled, it affects only XPRINT print operations. If XPRINT print attempts to display a character beyond the end of a row, it is automatically wrapped to the first column of the next row.

XPRINT$ function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET ATTACH statement New!

Purpose Retrieve the name of the attached host printer.

Syntax **XPRINT GET ATTACH TO *PrinterVar$***

Function Form:
***PrinterVar$* = XPRINT$(ATTACH)**
***PrinterVar$* = XPRINT$**

Remarks XPRINT GET ATTACH returns the name of the attached host printer, which is the printer that would be used by XPRINT statements. If there is no attached host printer, an empty string is returned. XPRINT$ is typically used to detect if an XPRINT ATTACH operation was successful.

See also XPRINT ATTACH

XPRINT$(ATTACH) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET ATTACH statement New!

Purpose Retrieve the name of the attached host printer.

Syntax `XPRINT GET ATTACH TO PrinterVar$`

Function Form:

```
PrinterVar$ = XPRINT$(ATTACH)
PrinterVar$ = XPRINT$
```

Remarks XPRINT GET ATTACH returns the name of the attached host printer, which is the printer that would be used by XPRINT statements. If there is no attached host printer, an empty string is returned. XPRINT$ is typically used to detect if an XPRINT ATTACH operation was successful.

See also XPRINT ATTACH

XPRINT$(PAPERS) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET PAPERS statement IMPROVED

Purpose Retrieves a list of supported paper types.

Syntax `XPRINT GET PAPERS TO PapersVar$`

Function Form:

```
PapersVar$ = XPRINT$(PAPERS)
```

Remarks XPRINT GET PAPERS retrieves a

which contains a list of all of the paper types supported by the attached host printer. This string is assigned to the string variable specified by *PapersVar$*.

The string contains a comma-delimited list of *papertype*, *papername*... repeated as many times as necessary. For example:

```
"1,Letter,5,Legal,7,Executive,20,Envelope #10"
```

You can use PARSECOUNT to determine the number of delimited fields in the string, and PARSE$() to easily extract the type numbers and names. The following equates are predefined in the compiler, and represent the most common paper styles:

```
%DMPAPER_LETTER    =  1     Letter    8.5   x 11    inches
%DMPAPER_TABLOID   =  3     Tabloid   11    x 17    inches
%DMPAPER_LEDGER    =  4     Ledger    17    x 11    inches
%DMPAPER_LEGAL     =  5     Legal     8.5   x 14    inches
%DMPAPER_STATEMENT =  6     Statement 5.5   x 8.5   inches
%DMPAPER_EXECUTIVE =  7     Executive 7.25  x 10.5  inches
%DMPAPER_A3        =  8     A3        297   x 420   mm
%DMPAPER_A4        =  9     A4        210   x 297   mm
```

```
%DMPAPER_A5         = 11      A5        148   x 210   mm
%DMPAPER_B4         = 12      B4        250   x 354   mm
%DMPAPER_B5         = 13      B5        182   x 257   mm
%DMPAPER_FOLIO      = 14      Folio     8.5   x 13    inches
%DMPAPER_QUARTO     = 15      Quarto    215   x 275   mm
%DMPAPER_10X14      = 16      10x14     10    x 14    inches
%DMPAPER_11X17      = 17      11x17     11    x 17    inches
%DMPAPER_NOTE       = 18      Note      8.5   x 11    inches
%DMPAPER_ENV_9      = 19      9 Envlp   3.875 x 8.875 inches
%DMPAPER_ENV_10     = 20      10 Envlp  4.125 x 9.5   inches
```

Other paper style codes may be defined by Windows or printer suppliers. If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET PAPERS, XPRINT SET PAPER

XPRINT$(TRAYS) function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET TRAYS statement IMPROVED

Purpose Retrieves a list of supported paper trays.

Syntax **XPRINT GET TRAYS TO *TrayVar$***

Function Form:
***TrayVar$* = XPRINT$(TRAYS)**

Remarks XPRINT GET TRAYS retrieves a

which contains a list of all of the paper trays supported by the attached host printer. This string is assigned to the string variable specified by *TrayVar$*.

The string contains a comma-delimited list of traytype, trayname... repeated as many times as necessary. For example:

```
"1,Upper,2,Lower,5,Envelope"
```

You can use PARSECOUNT to determine the number of delimited fields in the string, and PARSE$() to easily extract the tray numbers and names. The following equates are predefined in the compiler, and represent the most common trays:

```
%DMBIN_UPPER          = 1
%DMBIN_LOWER          = 2
%DMBIN_MIDDLE         = 3
%DMBIN_MANUAL         = 4
%DMBIN_ENVELOPE       = 5
%DMBIN_ENVMANUAL      = 6
%DMBIN_AUTO           = 7
%DMBIN_TRACTOR        = 8
%DMBIN_SMALLFMT       = 9
%DMBIN_LARGEFMT       = 10
%DMBIN_LARGECAPACITY  = 11
%DMBIN_CASSETTE       = 14
%DMBIN_FORMSOURCE     = 15
```

Other paper style codes may be defined by Windows or printer suppliers. If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET TRAY, XPRINT SET TRAY

XPRINT ARC statement

XPRINT ARC statement

Purpose Draw an arc on a host printer page.

Syntax **XPRINT ARC (*x1!*, *y1!*) - (*x2!*, *y2!*), *arcStart!*, *arcEnd!* [, *rgbColor&*]**

Remarks An arc is a section of a circle or an ellipse. To specify a particular arc, you would first define the full circle or ellipse of which it is a part, and then specify the points on the ellipse where the arc starts and stops.

The full circle or ellipse is defined by its bounding rectangle, which is the smallest rectangle which can be drawn around the circle or ellipse. For example, if the circle is centered at position (400,400), with a radius of 100 pixels, the upper left corner (x1,y1) of the bounding rectangle is (300,300), and the lower right corner (x2,y2) is (500,500).

The start point and end point of the arc are specified by their angle, which must be given in radians. A complete circle or ellipse is 2*pi radians. On a 12-hour clock-face, the values 0 and 2*pi both refer to the position of 3 o'clock, while the value 1*pi refers to the position of 9 o'clock. Other positions are specified by a radian value relative to these. In PowerBASIC, arcs are always drawn counter-clockwise from the starting point to the ending point.

Prior to any

operations, a host printer must first be selected with XPRINT ATTACH. The coordinate points are specified in pixels (or world coordinates, if those were chosen with XPRINT SCALE). Line width can be set using XPRINT WIDTH. If line width is set to 1 (the default), the line style can be set with XPRINT STYLE. Because of the nature of an arc, XPRINT ARC neither uses, nor updates, (last point referenced). If executed without a host printer attached, error 57 is generated.

x1!, *y1!* The upper left corner of the bounding rectangle of the full circle or ellipse.

x2!, *y2!* The lower right corner of the bounding rectangle of the full circle or ellipse.

ArcStart! The starting angle of the arc, in radians, from 0 to 2*pi.

ArcEnd! The ending angle of the arc, in radians, from 0 to 2*pi radians. Note that arcs are always drawn counter-clockwise from *arcStart!* to *arcEnd!*. Compared with a 12-hour clock-face, 0 or 2*pi radians is at 3 o'clock, and 1*pi radians is at 9 o'clock.

rgbColor& Optional RGB color for the arc. If omitted (or -1), the current foreground color for the host printer page is used.

See also Built In RGB Color Equates, XPRINT ATTACH, XPRINT COLOR, XPRINT ELLIPSE, XPRINT PIE, XPRINT STYLE, XPRINT WIDTH

Example

```
' Draw two arcs that combine into a circle.
' The upper half uses the default foreground color.
' The lower half is drawn in red.
LOCAL Pi AS DOUBLE
Pi = 4 * ATN(1)                            ' Calculate Pi
XPRINT ARC (5, 5) - (105, 105), 0,  Pi      ' Upper half
XPRINT ARC (5, 5) - (105, 105), Pi, 0, %RED ' Lower half
```

XPRINT ATTACH statement

XPRINT ATTACH statement IMPROVED

Purpose	Connect a host-based (GDI) printer for use with code.
Syntax	**XPRINT ATTACH {DEFAULT | *PrinterName$*} [,*JobName$*]** **XPRINT ATTACH CHOOSE [USING *Flags&*] [,*JobName$*]**
Remarks	XPRINT ATTACH connects to a host-based (Windows-only or GDI-based) printer for use with subsequent XPRINT operations. Host-based printing is device-independent and performed through the Windows printing system and printer driver. Device independence can be achieved because the printer driver handles the task of converting text into the manufacturers proprietary binary format used by the printer. To send device-dependent print data (such as plain text) to a line printer device, use the LPRINT ATTACH statement instead. XPRINT ATTACH allows you to change the printer device used by XPRINT operation. When executed, the current connection (if any) is closed and the new connection is established.
DEFAULT	If DEFAULT is specified, the default printer (as set in the Printers applet in Control Panel) is used. For example: **XPRINT ATTACH DEFAULT**
CHOOSE	If CHOOSE is specified, the Choose Printer common dialog is opened, allowing the user to select from the list of installed printers. For example: **XPRINT ATTACH CHOOSE** With CHOOSE, you may elect to include an optional numeric expression called *Flags&*. This value consists of one or more of the following equates to control the execution of the Printer Dialog:

%PD_ALLPAGES	"All Pages" button is the default.
%PD_SELECTION	"Selection" button is the default.
%PD_PAGENUMS	"Numbered Pages" button is the default. (Only one of the above is allowed)
%PD_NOSELECTION	Disables the "Selection" button.
%PD_NOPAGENUMS	Disables the "Numbered Pages" button.
%PD_COLLATE	"Collate" option is checked.
%PD_PRINTTOFILE	"Print To File" option is checked.
%PD_DISABLEPRINTTOFILE	Disables the "Print To File" option.
%PD_HIDEPRINTTOFILE	Hides the "Print To File" option.

PrinterName$	The name of the printer to attach (as shown in the Printers applet in Control Panel, or returned by the PRINTER$ function). *printername$* must be a valid device name and cannot exceed 259 characters in length. For example: **XPRINT ATTACH "HP LaserJet 5MP"**
JobName$	The name of the print job. This will be shown in the print spooler. If you do not supply a name, "Printjob" is used by default.

If XPRINT ATTACH is not successful, XPRINT$ returns an empty

. Error 68 ("device unavailable") is generated if an invalid printer was specified. No error is generated if the user cancels the Choose Printer dialog (with XPRINT ATTACH CHOOSE). Therefore, for host-based printing, applications should always use XPRINT ATTACH to explicitly select the intended host-based printer, then test for a successful selection with the XPRINT$ and ERR functions to ensure the host-based printer selection was successful.

Unlike direct printing (LPRINT ATTACH), host-based printing is handled by a printer driver and the operating system's spooler subsystem. Therefore, spooler settings such as "work offline" in the Printer Properties dialog will not impede the creation of a spooled print job. Once all the data has been sent to the printer, detach the printer so other applications can use it., with the XPRINT CLOSE statement.

Host-based printers use proprietary control protocols, unlike line printers, so it is usually not possible to send them printer-dependent control codes. To attach a line printer, use LPRINT ATTACH instead of XPRINT ATTACH.

Note: You can enumerate the available printers with the PRINTERCOUNT and PRINTER$ functions.

See also LPRINT ATTACH, PRINTER$, XPRINT CANCEL, XPRINT CLOSE, XPRINT GET ATTACH, XPRINT GET PAGES, XPRINT GET SELECTION

Example

```
ERRCLEAR
XPRINT ATTACH "HP DeskJet 960c"
IF ERR = 0 AND LEN(XPRINT$) > 0 THEN
  XPRINT COLOR RGB(0,0,255) ' Blue
  XPRINT "This is your printer talking"
  XPRINT FORMFEED           ' Issue a formfeed
  XPRINT CLOSE              ' Deselect the printer
END IF
```

XPRINT BOX statement

XPRINT BOX statement

Purpose Draw a box with square or rounded corners on a host printer page.

Syntax **XPRINT BOX (*x1!*, *y1!*) - (*x2!*, *y2!*) [, [*corner&*] [, [*rgbColor&*] [, [*fillcolor&*] [, [*fillstyle&*]]]]]**

Remarks Prior to any

operations, a host printer must first be selected with XPRINT ATTACH. The coordinate points are specified in pixels (or world coordinates, if those were chosen with XPRINT SCALE). Line width can be set using XPRINT WIDTH. If line width is set to 1 (the default), the line style can be set with XPRINT STYLE. Because of the nature of a box, XPRINT BOX neither uses, nor updates, (last point referenced). If executed without a host printer attached, error 57 is generated.

Windows graphic conventions consider the bottom and right coordinates of a BOX to be exclusive. The pixels at the bottom and right edges are not drawn unless OVERLAP MODE is enabled. See XPRINT SET OVERLAP for details.

x1!, *y1!* The upper left corner of the box.

x2!, *y2!* The lower right corner of the box.

corner& The percentage of roundness of the corners, in the range of 0 to 100. A value of zero creates square corners, while 100 creates a circle/oval. A value of 20 being most common for a pleasant, rounded appearance. If *corner&* is omitted, the default is 0, which creates a rectangle with square corners.

rgbColor&	Optional RGB color of the box edge. If omitted (or -1), the edge color defaults to the current foreground color for the host printer page.
fillcolor&	Optional RGB color of the box interior. If *fillcolor&* is omitted (or -2), the interior of the box is not filled, allowing the background to show through. If *fillcolor&* is -1, the interior is painted with the same color as the edge. Otherwise, *fillcolor&* specifies the RGB color to be used.
fillstyle&	Optional fill style (pattern) to be used. If *fillstyle&* is omitted, the default fill style is solid (0). If a hatch pattern is chosen (1 to 6), the foreground color is specified by the *fillcolor&*, while the background is specified by the default background color for the host printer page. The optional *fillstyle&* may be:

0	Solid (default)
1	Horizontal Lines
2	Vertical Lines
3	Upward Diagonal Lines
4	Downward Diagonal Lines
5	Crossed Lines
6	Diagonal Crossed Lines

See also Built In RGB Color Equates, XPRINT ATTACH, XPRINT COLOR, XPRINT LINE, XPRINT SET OVERLAP, XPRINT STYLE, XPRINT WIDTH

Example

```
' Draw rectangle with square corners and default colors.
XPRINT BOX (10, 10) - (100, 80)

' Draw a blue rectangle with 20% rounded corners,
' filled with a light-gray, diagonal cross pattern
XPRINT BOX (15, 15) - (95, 75), 20, %BLUE, RGB(191,191,191), 6
```

XPRINT CANCEL statement

XPRINT CANCEL statement

Purpose Cancel a print job on the host printer.

Syntax `XPRINT CANCEL`

Remarks XPRINT CANCEL deletes the current print job and detaches the host printer, as long as XPRINT CLOSE has not yet been executed. This function is generally used to abort the print process when an error occurs.

See also XPRINT ATTACH, XPRINT CLOSE

XPRINT CELL statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT CELL statement New!

Purpose Sets or retrieves the next print position (LPR - Last Point Referenced), based upon the row and column position of a text cell.

Syntax

```
XPRINT CELL = RowValue&, ColValue&
XPRINT CELL TO RowVar&, ColVar&
XPRINT COL TO ColVar&
XPRINT ROW TO RowVar&
```

```
Function Form:
ColVar& = XPRINT(COL)
RowVar& = XPRINT(ROW)
```

Remarks

XPRINT CELL is used to set or retrieve the print position, based upon the row and column position of a Text Cell. That is the row and column position where the next printed text will be displayed. *RowValue&* specifies the horizontal screen row (starting at 1) at which to position the cursor. *ColValue&* specifies the vertical screen column (starting at 1) at which to position the cursor. Since row and column numbers start at one (1), the upper left corner of the page is considered to be cell 1,1.

The first form of XPRINT CELL moves the print position to the desired row and column. If a value given is zero (0), that parameter is ignored and that position is not changed. The second form of XPRINT CELL retrieves the current print position, and assigns the values to the variables specified by *RowVar&* and *ColVar&*.

The remaining forms allow you to retrieve just a single value, either row or column, and are supported in both statement and function form.

XPRINT CELL SIZE, XPRINT SET FONT, XPRINT SET WORDWRAP, XPRINT SET WRAP, XPRINT SPLIT

XPRINT CELL SIZE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT CELL SIZE statement New!

Purpose

Retrieve the character cell size including external leading.

Syntax

```
XPRINT CELL SIZE TO WidthVar, HeightVar!
```

```
Function Form:
WidthVar!  = XPRINT(Cell.Size.X)
HeightVar! = XPRINT(Cell.Size.Y)
```

Remarks

XPRINT CELL SIZE retrieves the size of one character cell, for the current font, on the attached printer. The returned cell size is specified in PAGE UNITS, and allows you to calculate the number of text lines which will fit in a particular space. The height value is the size of the displayed character, including external leading (if any) for this particular font.

If the font is a fixed-width font, like Courier New or Lucida Console,the sizes returned are as exact as possible, given the fractional rounding approximations necessary for some scaled units. If the font is proportional, like Arial or Times New Roman, the width will be the average size for the entire font.

External leading is the vertical distance from the bottom of one character to the top of the character below it. This value is specified by the font in use. It may vary from zero to a larger value, depending upon the font and point size. To retrieve the exact height of characters without external leading, use XPRINT CHR SIZE.

See also XPRINT CELL, XPRINT CHR SIZE, XPRINT SET FONT, XPRINT TEXT SIZE

XPRINT CHR SIZE statement

XPRINT CHR SIZE statement IMPROVED

Purpose Retrieve the character size for the current font on a host printer page.

Syntax

```
XPRINT CHR SIZE TO WidthVar!, HeightVar!

Function Form:
WidthVar!  = XPRINT(Chr.Size.X)
HeightVar! = XPRINT(Chr.Size.Y)
```

Remarks The character size is specified in the same terms (pixels or scaled units) as originally stated. The height value retrieved is the actual size of the printed character without including any external leading for this particular font.

If the font is a fixed-width font, like Courier New or Lucida Console, the sizes returned are as exact as possible, given the fractional rounding approximations possible when converting from pixels to other coordinates. If the font is proportional, like Arial or Times New Roman, the width will be the average size for the entire font.

External leading is the vertical distance from the bottom of one character to the top of the character below it. This value is specified by the font in use. It may vary from zero to a larger value, depending upon the font and point size. To retrieve the total row height including external leading, use XPRINT CELL SIZE.

See also XPRINT, XPRINT ATTACH, XPRINT CELL SIZE, XPRINT SET FONT, XPRINT TEXT SIZE

XPRINT CLOSE statement

XPRINT CLOSE statement

Purpose Detach a host printer so printing may begin.

Syntax `XPRINT CLOSE`

Remarks XPRINT CLOSE detaches the printer from the current process, and allows printing to a HOST printer to begin. If XPRINT CLOSE is not executed, printed data may be lost.

See also XPRINT ATTACH, XPRINT CANCEL

XPRINT COLOR statement

XPRINT COLOR statement IMPROVED

Purpose Set the foreground color (and, optionally, the background color) for various statements.

Syntax `XPRINT COLOR foreground& [, background&]`

Remarks Colors are expressed as RGB values, or use -1 for the default color. If the background parameter is -2, the background is made transparent. If either parameter is -3, the existing color is not changed. A host printer must first be connected with XPRINT ATTACH. If a host printer is not attached, error 57 is generated.

See also Built In RGB Color Equates, XPRINT, XPRINT ATTACH

Example

```
' Set colors to red foreground and blue background.
```

```
XPRINT COLOR %RED, RGB(0,0,191)
```

XPRINT COPY statement

XPRINT COPY statement

Purpose Copy a

to a host printer page.

Syntax

XPRINT COPY ***hbmpSource???, id&*** **[,** ***style&*****]**
XPRINT COPY ***hbmpSource???, id&*** **TO (*****x!, y!*****) [,** ***style&*****]**
XPRINT COPY ***hbmpSource???, id&*****, (*****x1!, y1!*****)-(*****x2!, y2!*****) TO (*****x!, y!*****) [,** ***style %*****]**

Remarks You can copy a complete bitmap, or a portion of it, to the host printer page. The expression *hbmpSource???* specifies the handle of the source bitmap or window. The expression *id&* is the unique control identifier in the range 1 to 65535, as assigned with the CONTROL ADD GRAPHIC statement. *id&* must be 0 for a GRAPHIC WINDOW or a

. The destination of the copy operation is the host printer page. You must use care that your parameters are valid for the specified bitmaps, or results of the operation are undefined.

The first form of the XPRINT COPY statement copies the complete bitmap, positioning it at (0,0), which is the upper left corner of the destination.

The second form of XPRINT COPY also copies the complete bitmap, but positions it at the point specified by the parameter (*x!*, *y!*).

The third form copies a portion of the bitmap, positioning it at the point specified by the parameter (*x!*, *y!*). If *style&* is included, it is one of the following values:

%mix_Blackness	Pixel is always 0 (black).
%mix_NotMergeSrc	Pixel is the inverse of the MergeSrc color.
%mix_MaskNotSrc	Pixel is a combination of the colors common to both the pixel and the inverse of the source.
%mix_NotCopySrc	Pixel is the inverse of the pen color.
%mix_MaskSrcNot	Pixel is a combination of the colors common to both the source and the inverse of the pixel.
%mix_Not	Pixel is the inverse of the pixel color.
%mix_XorSrc	Pixel is a combination of the colors in the source and in the pixel, but not in both.
%mix_NotMaskSrc	Pixel is the inverse of the MaskSrc color.
%mix_MaskSrc	Pixel is a combination of the colors common to both the source and the pixel.
%mix_NotXorSrc	Pixel is the inverse of the XorSrc color.
%mix_Nop	Pixel remains unchanged.
%mix_MergeNotSrc	Pixel is a combination of the source color and the inverse of the pixel color.
%mix_CopySrc	Pixel is the source color (default).
%mix_MergeSrcNot	Pixel is a combination of the source color and the inverse of the pixel color.
%mix_MergeSrc	Pixel is a combination of the source color and the pixel color.
%mix_Whiteness	Pixel is always 1 (white).

A host printer must first be connected with XPRINT ATTACH. If a host printer is not attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT RENDER, XPRINT STRETCH, XPRINT SET STRETCHMODE

XPRINT ELLIPSE statement

XPRINT ELLIPSE statement

Purpose Draw an ellipse or a circle on a host printer page.

Syntax `XPRINT ELLIPSE (x1!, y1!) - (x2!, y2!) [, [rgbColor&] [, [fillcolor&] [, [fillstyle&]]]]`

Remarks A host printer must first be connected with XPRINT ATTACH. The coordinate points are specified in pixels (or world coordinates, if those were defined with an XPRINT SCALE statement). Line width can be set using XPRINT WIDTH. If line width is set to 1 (the default), the line style can be set with XPRINT STYLE. Because of the nature of an ellipse, which has no obvious beginning or end, XPRINT ELLIPSE neither uses, nor updates, the last point referenced (POS). If executed without a host printer attached, error 57 is generated.

The coordinate pair define an invisible bounding rectangle which would enclose the ellipse to be drawn. It tells both the size and the proportions of the ellipse. Windows graphic conventions consider the bottom and right coordinates of it to be exclusive. The pixels at the bottom and right edges are ignored, unless Overlap Mode is enabled. See XPRINT SET OVERLAP for details.

x1!, *y1!* The upper left corner of the bounding rectangle.

x2!, *y2!* The lower right corner of the bounding rectangle.

rgbColor& Optional RGB color of the ellipse edge. If omitted (or -1), the edge color defaults to the current foreground color for the host printer page.

fillcolor& Optional RGB color of the ellipse interior. If *fillcolor&* is omitted (or -2), the interior of the ellipse is not filled, allowing the background to show through. If *fillcolor&* is -1, the interior is painted with the same color as the edge. Otherwise, *fillcolor&* specifies the RGB color to be used.

fillstyle& Optional fill style (pattern) to be used. If *fillstyle&* is omitted, the default fill style is solid (0). If a hatch pattern is chosen (1 to 6), the foreground color is specified by the *fillcolor&*, while the background is specified by the default background color for the host printer page. The optional *fillstyle&* may be:

0	Solid (default)
1	Horizontal Lines
2	Vertical Lines
3	Upward Diagonal Lines
4	Downward Diagonal Lines
5	Crossed Lines
6	Diagonal Crossed Lines

See also Built In RGB Color Equates, XPRINT ARC, XPRINT ATTACH, XPRINT COLOR, XPRINT LINE, XPRINT PIE, XPRINT SET OVERLAP, RINT STYLE, XPRINT WIDTH

Example

```
' Draw a circle, using default colors.
XPRINT ELLIPSE (10, 10) - (100, 100)
' Draw a blue ellipse filled with a light-gray, diagonal cross pattern.
XPRINT ELLIPSE (15, 25) - (95, 50), %BLUE, RGB(191,191,191), 6
```

XPRINT FORMFEED statement

XPRINT FORMFEED statement

Purpose Start a new page for the host printer.

Syntax `XPRINT FORMFEED`

Remarks XPRINT FORMFEED causes the current print page to be ejected, and a new page started. If XPRINT FORMFEED is unsuccessful, an error is generated. Note that some printers do not eject a page if it is blank.

See also XPRINT ATTACH, XPRINT CLOSE

XPRINT GET ATTACH statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET ATTACH statement New!

Purpose Retrieve the name of the attached host printer.

Syntax

```
XPRINT GET ATTACH TO PrinterVar$

Function Form:
PrinterVar$ = XPRINT$(ATTACH)
PrinterVar$ = XPRINT$
```

Remarks XPRINT GET ATTACH returns the name of the attached host printer, which is the printer that would be used by XPRINT statements. If there is no attached host printer, an empty string is returned. XPRINT$ is typically used to detect if an XPRINT ATTACH operation was successful.

See also XPRINT ATTACH

XPRINT GET CANVAS statement

XPRINT GET CANVAS statement New!

Purpose Retrieves the writable size of the attached host printer.

Syntax

```
XPRINT GET CANVAS TO WidthVar!, HeightVar!

Function Form:
WidthVar!  = XPRINT(CANVAS.X)
HeightVar! = XPRINT(CANVAS.Y)
```

Remarks XPRINT GET CANVAS retrieves the logical size of the client area (printable area) for the attached host printer. This is the size of the page, minus the unprintable margins, without any reductions for a CLIP area. The size is specified in Page Units, so it could return scaled values if they were applied with XPRINT SCALE. This is very similar to XPRINT GET CLIENT, with the single exception that scaled values (set by XPRINT SCALE) are returned if they have been utilized. If executed without a host printer attached, error 57 is generated.

See also XPRINT GET CLIENT, XPRINT GET CLIP, XPRINT GET SIZE, XPRINT GET SCALE, XPRINT SCALE

XPRINT GET CLIENT statement

XPRINT GET CLIENT statement IMPROVED

Purpose Retrieves the size of the client area (printable area) on the host printer page.

Syntax
```
XPRINT GET CLIENT To WidthVar!, HeightVar!

Function Form:
WidthVar!  = XPRINT(Client.X)
HeightVar! = XPRINT(Client.Y)
```

Remarks XPRINT GET CLIENT retrieves the physical size of the client area (printable area) for the attached host printer. The size is always specified in Pixels (points). This is very similar to XPRINT GET CANVAS, with the single exception that scaled values (set by XPRINT SCALE) are not utilized. If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET CANVAS, XPRINT GET CLIP, XPRINT GET MARGIN, XPRINT GET PPI, XPRINT GET SIZE

XPRINT GET CLIP statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET CLIP statement New!

Purpose Retrieves the size of the clip area on the selected printer.

Syntax
```
XPRINT GET CLIP TO WidthVar!, HeightVar!

Function Form:
WidthVar!  = XPRINT(Clip.X)
HeightVar! = XPRINT(Clip.Y)
```

Remarks The clip area of the printer is that space where print operations can be written. That is, the clip area is that portion of the client area which is not protected (clipped) by the XPRINT SET CLIP statement.

XPRINT GET CLIP retrieves the size of the clip area, and assigns these values to the variables specified by *WidthVar!* and *HeightVar!*. The size is specified in PAGE UNITS (pixels/points or scaled units). If no printer is selected, the values 0,0 are returned.

See also XPRINT GET CANVAS, XPRINT GET CLIENT, XPRINT SET CLIP

XPRINT GET COLLATE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET COLLATE statement IMPROVED

Purpose Retrieves the XPRINT collate status.

Syntax
```
XPRINT GET COLLATE TO CollateVar&

Function Form:
CollateVar& = XPRINT(COLLATE)
```

Remarks XPRINT allows you to set the collate status, if the printer driver supports both multiple copies and collate capability. XPRINT GET COLLATE retrieves the collate status, assigning the value to the long integer variable specified by *CollateVar&*. The following equates are predefined in the compiler to symbolically represent the possible collate status:

```
%DMCOLLATE_FALSE        = 0
%DMCOLLATE_TRUE         = 1
```

If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT SET COLLATE

XPRINT GET COLORMODE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET COLORMODE statement IMPROVED

Purpose Retrieves the XPRINT colormode status.

Syntax
```
XPRINT GET COLORMODE TO ColorVar&

Function Form:
ColorVar& = XPRINT(COLORMODE)
```

Remarks XPRINT allows you to set the color or monochrome print mode if the printer driver supports it. XPRINT GET COLORMODE retrieves the colormode status, assigning the value to the long integer variable specified by *ColorVar&*. The value zero may be returned if colormode is not supported by the printer driver. The following equates are predefined in the compiler to symbolically represent the possible status:

```
%DMCOLOR_MONOCHROME     = 1
%DMCOLOR_COLOR          = 2
```

If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT SET COLORMODE

XPRINT GET COPIES statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET COPIES statement IMPROVED

Purpose Retrieves the XPRINT copy count.

Syntax **XPRINT GET COPIES TO *CopyVar&***

Function Form:

***CopyVar&* = XPRINT(COPIES)**

Remarks XPRINT allows you to set the number of copies to be automatically printed, if it is supported by the printer driver. XPRINT GET COPIES retrieves the copy count, assigning the value to the long integer variable specified by *CopyVar&*. The default value is one (1). If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT SET COPIES

XPRINT GET DC statement

XPRINT GET DC statement IMPROVED

Purpose Retrieve the handle of the device context (DC) for the host printer page.

Syntax **XPRINT GET DC TO *hDC***

Function Form:
***hDC* = XPRINT(DC)**

Remarks If no host printer is currently attached, zero is returned. The DC handle may be used with various Windows API functions to perform specialized operations on the host printer page.

See also XPRINT ATTACH

XPRINT GET DUPLEX statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET DUPLEX statement IMPROVED

Purpose Retrieve the XPRINT duplex status.

Syntax **XPRINT GET DUPLEX TO *DuplexVar&***

Function Form:
***DuplexVar&* = XPRINT(DUPLEX)**

Remarks XPRINT allows you to get/set the duplex status, if the printer supports printing on both sides of a page. XPRINT GET DUPLEX retrieves the duplex status, assigning the value to the long integer variable specified by *DuplexVar&*. The following equates are predefined in the compiler to symbolically represent the possible duplex status:

```
%DMDUP_SIMPLEX        = 1    (single sided printing)
%DMDUP_VERTICAL       = 2    (page flipped on the vertical edge)
%DMDUP_HORIZONTAL     = 3    (page flipped on the horizontal edge)
```

If the printer does not support duplex printing, the value zero (0) is returned. If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT SET DUPLEX

XPRINT GET LINES statement

XPRINT GET LINES statement IMPROVED

Purpose Retrieve the number of lines that can be printed.

Syntax

```
XPRINT GET LINES To LineVar&
Function Form:
LineVar& = XPRINT(LINES)
```

Remarks XPRINT GET LINES retrieves the number of lines of text which can be printed on the host printer page, given the current selected font. Since

statements do not generate an automatic formfeed when text is printed on the last line, this statement can be used to determine when your program should execute an XPRINT FORMFEED to move to the next printed page on a host printer. If executed without a host printer attached, error 57 is generated.

See also XPRINT, XPRINT ATTACH, XPRINT SET FONT, XPRINT FORMFEED

XPRINT GET MARGIN statement

XPRINT GET MARGIN statement

Purpose Retrieve the margin sizes for the host printer.

Syntax

```
XPRINT GET MARGIN TO nLeft!, nTop!, nRight!, nBottom!
```

Remarks XPRINT GET MARGIN retrieves the size of the margins (the non-printable area) of the printer page. This is important because some printers do not provide equal margins on each side of the page. This is more common on the vertical coordinate, but could be found in either or both directions. The size of the four margins are specified in pixels (or world coordinates, if those were defined with an XPRINT SCALE statement). If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET CLIENT, XPRINT GET PPI, XPRINT GET SIZE

XPRINT GET MIX statement

XPRINT GET MIX statement IMPROVED

Purpose Retrieve the color mix mode for a host printer page.

Syntax

```
XPRINT GET MIX To MixVar&
Function Form:
MixVar& = XPRINT(MIX)
```

Remarks Prior to any

operations, a host printer must first be selected with XPRINT ATTACH. There are 16 mix modes available to use for mixing the drawing color with the color that already exists at the drawing location. The mix mode equates are predefined in PowerBASIC. If executed without a host printer attached, error 57 is generated.

%MIX_BLACKNESS	Pixel is always 0 (black).
%MIX_NOTMERGESRC	Pixel is the inverse of the MergeSrc color.
%MIX_MASKNOTSRC	Pixel is a combination of the colors common to both the pixel and the inverse of the source.
%MIX_NOTCOPYSRC	Pixel is the inverse of the pen color.
%MIX_MASKSRCNOT	Pixel is a combination of the colors common to both the source and the inverse of the pixel.
%MIX_NOT	Pixel is the inverse of the pixel color.
%MIX_XORSRC	Pixel is a combination of the colors in the source and in the pixel, but not in both.
%MIX_NOTMASKSRC	Pixel is the inverse of the MaskSrc color.
%MIX_MASKSRC	Pixel is a combination of the colors common to both the source and the pixel.
%MIX_NOTXORSRC	Pixel is the inverse of the XorSrc color.
%MIX_NOP	Pixel remains unchanged.
%MIX_MERGENOTSRC	Pixel is a combination of the source color and the inverse of the pixel color.
%MIX_COPYSRC	Pixel is the source color (default).
%MIX_MERGESRCNOT	Pixel is a combination of the source color and the inverse of the pixel color.
%MIX_MERGESRC	Pixel is a combination of the source color and the pixel color.
%MIX_WHITENESS	Pixel is always 1 (white).

See also XPRINT ATTACH, XPRINT SET MIX

XPRINT GET ORIENTATION statement

XPRINT GET ORIENTATION statement IMPROVED

Purpose Retrieve the paper orientation for a host printer page.

Syntax

```
XPRINT GET ORIENTATION To OrentVar&
Function Form:
OrentVar& = XPRINT(ORIENTATION)
```

Remarks XPRINT GET ORIENTATION retrieves the orientation of the paper in the host printer, assigning the value to the long integer variable specified by *OrentVar&*. The value 1 indicates portrait mode, while 2 indicates landscape mode. If the printer does not support paper orientation, 0 is returned. If a host printer is not attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT SET ORIENTATION

XPRINT GET OVERLAP statement

XPRINT GET OVERLAP statement New!

Purpose Retrieves the status of XPrint Overlap Mode.

Syntax

```
XPRINT GET OVERLAP To OverlapVar&
Function Form:
OverlapVar& = XPRINT(OVERLAP)
```

Remarks XPRINT GET OVERLAP retrieves the status of overlap mode and assigns it to the variable specified by *OverlapVar&*. If Overlap Mode is enabled, the value true (non-zero) is assigned. If it's disabled, the value false (zero) is assigned instead. The value returned reflects the status of the host printer which is currently attached to the XPrint stream.

With Overlap Mode, you can control how PowerBASIC treats XPrint operations which involve a bounding rectangle (RECT structure) in their definition. Windows maintains unique conventions for a RECT. The bottom and right coordinates of a RECT are exclusive. In other words, the pixels at the bottom and right edges lie immediately outside the rectangle. They are ignored. For example:

```
XPRINT BOX (0,0) - (50,50)
```

In this case, a box is drawn from 0,0 to 49,49. The final pixels at the bottom and right edge are simply not drawn. However, if Overlap Mode is enabled with XPRINT SET OVERLAP, the box is drawn from 0,0 to 50,50.

The Overlap Mode affects all XPRINT functions which take a bounding rectangle as a parameter. This includes XPRINT SCALE, XPRINT BOX, XPRINT ELLIPSE, XPRINT LINE, XPRINT POLYLINE, etc.

See also XPRINT SET OVERLAP

XPRINT GET PAGES statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET PAGES statement New!

Purpose Retrieves the XPRINT page number limits for this print job.

Syntax **XPRINT GET PAGES TO *FromPage&, ToPage&***

Remarks You may elect to limit a particular print job to a subset of the total number of pages. This can be accomplished under program control by executing XPRINT SET PAGES, or the user can make the appropriate choice in the Print Dialog which is displayed when XPRINT ATTACH is executed with the CHOOSE option. When the pages are limited in this way, PowerBASIC handles all the details of print suppression for you.

Normally, XPRINT pages are numbered from one. The parameter *FromPage&* specifies the first page of the full report which will be printed, while *ToPage&* specifies the last page.

If XPRINT GET PAGES is executed without a host printer attached, an error 57 is generated.

See also XPRINT PREVIEW, XPRINT GET SELECTION, XPRINT SET PAGES

XPRINT GET PAPER statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET PAPER statement IMPROVED

Purpose Retrieves the current paper size/type.

Syntax

```
XPRINT GET PAPER TO PaperVar&

Function Form:
PaperVar& = XPRINT(PAPER)
```

Remarks XPRINT GET PAPER retrieves the paper style for which the host printer is currently configured. The paper style is identified by an

value which is assigned to the long integer variable specified by *PaperVar&*. The following equates are predefined in the compiler, and represent the most common paper styles:

```
%DMPAPER_LETTER    =  1     Letter    8.5   x 11    inches
%DMPAPER_TABLOID   =  3     Tabloid   11    x 17    inches
%DMPAPER_LEDGER    =  4     Ledger    17    x 11    inches
%DMPAPER_LEGAL     =  5     Legal     8.5   x 14    inches
%DMPAPER_STATEMENT =  6     Statement 5.5   x 8.5   inches
%DMPAPER_EXECUTIVE =  7     Executive 7.25  x 10.5  inches
%DMPAPER_A3        =  8     A3        297   x 420   mm
%DMPAPER_A4        =  9     A4        210   x 297   mm
%DMPAPER_A5        = 11     A5        148   x 210   mm
%DMPAPER_B4        = 12     B4        250   x 354   mm
%DMPAPER_B5        = 13     B5        182   x 257   mm
%DMPAPER_FOLIO     = 14     Folio     8.5   x 13    inches
%DMPAPER_QUARTO    = 15     Quarto    215   x 275   mm
%DMPAPER_10X14     = 16     10x14     10    x 14    inches
%DMPAPER_11X17     = 17     11x17     11    x 17    inches
%DMPAPER_NOTE      = 18     Note      8.5   x 11    inches
%DMPAPER_ENV_9     = 19     9 Envlp   3.875 x 8.875 inches
%DMPAPER_ENV_10    = 20     10 Envlp  4.125 x 9.5   inches
```

Other paper style codes may be defined by Windows or printer suppliers. You can use XPRINT GET PAPERS to obtain a list of all the paper styles supported by the attached host printer.

If the printer does not support paper style changes, the value zero is returned. If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET PAPERS, XPRINT SET PAPER

XPRINT GET PAPERS statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET PAPERS statement IMPROVED

Purpose Retrieves a list of supported paper types.

Syntax `XPRINT GET PAPERS TO PapersVar$`

Function Form:
`PapersVar$ = XPRINT$(PAPERS)`

Remarks XPRINT GET PAPERS retrieves a

which contains a list of all of the paper types supported by the attached host printer. This string is assigned to the string variable specified by *PapersVar$*.

The string contains a comma-delimited list of *papertype*, *papername*... repeated as many times as necessary. For example:

```
"1,Letter,5,Legal,7,Executive,20,Envelope #10"
```

You can use PARSECOUNT to determine the number of delimited fields in the string, and PARSE$() to easily extract the type numbers and names. The following equates are predefined in the compiler, and represent the most common paper styles:

```
%DMPAPER_LETTER    =  1      Letter    8.5   x 11    inches
%DMPAPER_TABLOID   =  3      Tabloid   11    x 17    inches
%DMPAPER_LEDGER    =  4      Ledger    17    x 11    inches
%DMPAPER_LEGAL     =  5      Legal     8.5   x 14    inches
%DMPAPER_STATEMENT =  6      Statement 5.5   x 8.5   inches
%DMPAPER_EXECUTIVE =  7      Executive 7.25  x 10.5  inches
%DMPAPER_A3        =  8      A3        297   x 420   mm
%DMPAPER_A4        =  9      A4        210   x 297   mm
%DMPAPER_A5        = 11      A5        148   x 210   mm
%DMPAPER_B4        = 12      B4        250   x 354   mm
%DMPAPER_B5        = 13      B5        182   x 257   mm
%DMPAPER_FOLIO     = 14      Folio     8.5   x 13    inches
%DMPAPER_QUARTO    = 15      Quarto    215   x 275   mm
%DMPAPER_10X14     = 16      10x14     10    x 14    inches
%DMPAPER_11X17     = 17      11x17     11    x 17    inches
%DMPAPER_NOTE      = 18      Note      8.5   x 11    inches
%DMPAPER_ENV_9     = 19      9 Envlp   3.875 x 8.875 inches
%DMPAPER_ENV_10    = 20      10 Envlp  4.125 x 9.5   inches
```

Other paper style codes may be defined by Windows or printer suppliers. If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET PAPERS, XPRINT SET PAPER

XPRINT GET PIXEL statement

XPRINT GET PIXEL statement IMPROVED

Purpose Retrieves the color of a pixel on a host printer page.

Syntax `XPRINT GET PIXEL [STEP] (x!, y!) TO PixelVar&`

Function Form:
`PixelVar& = XPRINT(PIXEL [STEP], x!, y!)`

Remarks Not all printer drivers support the ability to retrieve the color of a pixel. If this feature is not supported, or if the coordinates are outside the printer client area, an invalid color value of -1 is returned. If no host printer is attached, error 57 is generated.

See also Built In RGB Color Equates, XPRINT ATTACH, XPRINT COLOR, XPRINT SET PIXEL

XPRINT GET POS statement

XPRINT GET POS statement IMPROVED

Purpose Retrieves the last point referenced (POS) by an statement.

Syntax
```
XPRINT GET POS TO XVar!, YVar!
Function Form:
XVar! = XPRINT(POS.X)
YVar! = XPRINT(POS.Y)
```

Remarks XPRINT GET POS allows you to retrieve the last point referenced (POS) by XPRINT statements. The coordinate points are specified in Page Units. If executed without a host printer attached, an error 57 is generated, and the values 0,0 are returned.

See also XPRINT ATTACH, XPRINT SET POS

XPRINT GET PPI statement

XPRINT GET PPI statement IMPROVED

Purpose Retrieves the resolution of the host printer page.

Syntax
```
XPRINT GET PPI TO XVar&, YVar&
Function Form:
XVar& = XPRINT(PPI.X)
YVar& = XPRINT(PPI.Y)
```

Remarks XPRINT GET PPI retrieves the resolution (points per inch) of the host printer page. The resolution is always specified in pixels, regardless of any XPRINT SCALE option. If executed without a host printer attached, error 57 is generated, and the values 0,0 are returned. This statement is particularly useful in drawing items such as rulers and graphs to a particular physical size. There are 25.4 millimeters per inch, so just divide by 25.4 to convert from pixels per inch to pixels per millimeter.

See also XPRINT ATTACH, XPRINT GET CLIENT, XPRINT GET MARGIN, XPRINT GET SIZE

XPRINT GET QUALITY statement

XPRINT GET QUALITY statement IMPROVED

Purpose Retrieves the print quality setting for the host printer.

Syntax
```
XPRINT GET QUALITY To QualVar&
Function Form:
QualVar& = XPRINT(QUALITY)
```

Remarks XPRINT GET QUALITY retrieves the print quality setting for the host printer. The value 1 is draft mode, 2 is low resolution, 3 is medium resolution, and 4 is high resolution. If the printer does not support print quality settings, 0 is returned. If no host printer is attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT SET QUALITY

XPRINT GET SCALE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET SCALE statement

Purpose Retrieve the current coordinate limits for the host printer page.

Syntax `XPRINT GET SCALE TO x1!, y1!, x2!, y2!`

Remarks XPRINT SCALE allows you to define your own world coordinate system for subsequent statements. World coordinates may be values, with the only requirement that *x1!* not equal *x2!*, and *y1!* not equal *y2!*.

XPRINT GET SCALE retrieves the coordinate limits, which may be either custom world coordinates (if an XPRINT SCALE has been executed), or else default pixel coordinates. This allows you to save and restore a previous set of coordinates.

See also XPRINT SCALE, XPRINT SCALE PIXELS

XPRINT GET SELECTION statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET SELECTION statement New!

Purpose Retrieves the status of the SELECTION flag.

Syntax `XPRINT GET SELECTION TO SelectVar&`

Function Form:
`SelectVar& = XPRINT(SELECTION)`

Remarks You may elect to limit a particular print job to just that part of the total which is selected/highlighted. If so, it is the programmer's responsibility to limit XPRINT output to just the selected region.

The selection flag can only be set by the user in the Print Dialog which is displayed when XPRINT ATTACH is executed with the CHOOSE option. It cannot be set under program control. This flag is maintained only to give the programmer information about the user's request. If you do not wish to honor this option, you should disable it in XPRINT ATTACH CHOOSE.

If XPRINT GET SELECTION is executed without a host printer attached, an error 57 is generated.

See also XPRINT ATTACH

XPRINT GET SIZE statement

XPRINT GET SIZE statement IMPROVED

Purpose Retrieve the total size of the host printer page.

Syntax

```
XPRINT GET SIZE TO WidthVar&, HeightVar&
Function Form:
WidthVar&  = XPRINT(SIZE.X)
HeightVar& = XPRINT(SIZE.Y)
```

Remarks XPRINT GET SIZE allows you to retrieve the full size of the host printer page, including both the printable client area and any unprintable margins. The sizes are specified in pixels (points). If no host printer is attached, error 57 is generated, and the values 0,0 are returned.

See also XPRINT ATTACH, XPRINT GET CLIENT, XPRINT GET MARGIN, XPRINT GET MIX, XPRINT GET PPI

XPRINT GET STRETCHMODE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET STRETCHMODE statement New!

Purpose Retrieves the default bitmap stretching mode for the attached DC.

Syntax

```
XPRINT GET STRETCHMODE TO ModeVar&
Function Form:
ModeVar& = XPRINT(STRETCHMODE)
```

Remarks There are several operations in PowerBASIC which involve stretching or condensing images on bitmaps, most notably XPRINT STRETCH. As individual points must be added or removed, there is a good chance that the quality of the image will be degraded. However, if you describe the nature of the image by defining a StretchMode, you can substantially enhance the appearance.

The default StretchMode is maintained individually for each DC. You can retrieve the default mode with this statement, or set it with XPRINT SET STRETCHMODE. Of course, you can also override the default StretchMode when you execute one of the affected statements.

The 4 stretch mode equates are predefined in PowerBASIC.

%BLACKONWHITE	1	This is the default Windows stretch mode, and is most appropriate for monochrome bitmaps, or those with blocks of color. Performs a boolean OR of eliminated and existing pixels. It preserves black pixels at the expense of white pixels.
%	2	Performs a boolean OR of eliminated and existing pixels. It

WHITEONBLACK		preserves white pixels at the expense of black pixels.
%COLORONCOLOR	3	Deletes eliminated lines of pixels without trying to preserve their information.
%HALFTONE	4	This provides the highest quality for complex color bitmaps. The average color of the destination pixel block is kept approximately the same as the source pixel block.

See also XPRINT COPY, XPRINT RENDER, XPRINT STRETCH, XPRINT SET STRETCHMODE

XPRINT GET TRAY statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET TRAY statement IMPROVED

Purpose Retrieves the active printer tray.

Syntax

```
XPRINT GET TRAY TO TrayVar&
```

Function Form:

```
TrayVar& = XPRINT(TRAY)
```

Remarks XPRINT GET TRAY retrieves the paper tray which is active on the host printer. A descriptive value is assigned to the long integer variable specified by *TrayVar&*. The following equates are predefined in the compiler, and represent the most common paper trays:

```
%DMBIN_UPPER         = 1
%DMBIN_LOWER         = 2
%DMBIN_MIDDLE        = 3
%DMBIN_MANUAL        = 4
%DMBIN_ENVELOPE      = 5
%DMBIN_ENVMANUAL     = 6
%DMBIN_AUTO          = 7
%DMBIN_TRACTOR       = 8
%DMBIN_SMALLFMT      = 9
%DMBIN_LARGEFMT      = 10
%DMBIN_LARGECAPACITY = 11
%DMBIN_CASSETTE      = 14
%DMBIN_FORMSOURCE    = 15
```

Other tray codes may be defined by Windows or printer suppliers, so your program should be written to consider that possibility. You can use XPRINT GET TRAYS to obtain a list of all the paper trays supported by the attached host printer.

If the printer does not support the tray change requested, error 5 is generated. If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET TRAYS, XPRINT SET TRAY

XPRINT GET TRAYS statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET TRAYS statement IMPROVED

Purpose Retrieves a list of supported paper trays.

Syntax

```
XPRINT GET TRAYS TO TrayVar$
```

Function Form:

```
TrayVar$ = XPRINT$(TRAYS)
```

Remarks XPRINT GET TRAYS retrieves a

which contains a list of all of the paper trays supported by the attached host printer. This string is assigned to the string variable specified by *TrayVar$*.

The string contains a comma-delimited list of traytype, trayname... repeated as many times as necessary. For example:

```
"1,Upper,2,Lower,5,Envelope"
```

You can use PARSECOUNT to determine the number of delimited fields in the string, and PARSE$() to easily extract the tray numbers and names. The following equates are predefined in the compiler, and represent the most common trays:

```
%DMBIN_UPPER         = 1
%DMBIN_LOWER         = 2
%DMBIN_MIDDLE        = 3
%DMBIN_MANUAL        = 4
%DMBIN_ENVELOPE      = 5
%DMBIN_ENVMANUAL     = 6
%DMBIN_AUTO          = 7
%DMBIN_TRACTOR       = 8
%DMBIN_SMALLFMT      = 9
%DMBIN_LARGEFMT      = 10
%DMBIN_LARGECAPACITY = 11
%DMBIN_CASSETTE      = 14
%DMBIN_FORMSOURCE    = 15
```

Other paper style codes may be defined by Windows or printer suppliers. If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET TRAY, XPRINT SET TRAY

XPRINT GET WORDWRAP statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET WORDWRAP statement New!

Purpose Retrieves the status of XPRINT WordWrap Mode.

Syntax
```
XPRINT GET WORDWRAP TO WrapVar&
```
Function Form:
```
WrapVar& = XPRINT(WORDWRAP)
```

Remarks XPRINT GET WORDWRAP retrieves the status of wordwrap mode and assigns it to the variable specified by *WrapVar&*. If WordWrap Mode is enabled, the value true (non-zero) is assigned. If it's disabled, the value false (zero) is assigned instead. The value returned reflects the status of the attached printer.

With WordWrap Mode, you can control how PowerBASIC prints text on an XPRINT page when it reaches the end of a line. Since XPRINT operates on a full page basis, the default is to ignore text which is printed past the end of the line. This can be modified under program control by using XPRINT SET WORDWRAP.

When WordWrap mode is enabled, it affects only XPRINT print operations. If XPRINT print attempts to display a word beyond the end of a row, the entire word is automatically wrapped to the first column of the next row.

See also XPRINT CELL, XPRINT GET WRAP, XPRINT SET WORDWRAP, XPRINT SET WRAP, XPRINT SPLIT

XPRINT GET WRAP statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT GET WRAP statement New!

Purpose Retrieves the status of XPRINT Wrap Mode.

Syntax
```
XPRINT GET WRAP TO WrapVar&
```
Function Form:
```
WrapVar& = XPRINT(WRAP)
```

Remarks XPRINT GET WRAP retrieves the status of wrap mode and assigns it to the variable specified by *WrapVar&*. If Wrap Mode is enabled, the value true (non-zero) is assigned. If it's disabled, the value false (zero) is assigned instead. The value returned reflects the status of the attached printer.

With Wrap Mode, you can control how PowerBASIC prints text on an XPRINT page when it reaches the end of a line. Since XPRINT operates on a full page basis, the default is to ignore text which is printed past the end of the line. This can be modified under program control by using XPRINT SET WRAP.

When Wrap Mode is enabled, it affects only XPRINT print operations. If XPRINT print attempts to display a character beyond the end of a row, it is automatically wrapped to the first column of the next row.

See also XPRINT CELL, XPRINT GET WORDWRAP, XPRINT SET WORDWRAP, XPRINT SET WRAP, XPRINT SPLIT

XPRINT IMAGELIST statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT IMAGELIST statement

Purpose Prints an image from an IMAGELIST

Syntax `XPRINT IMAGELIST (x!,y!), hLst, index&, overlay&, style&`

Remarks One of the images stored in an IMAGELIST is printed on the attached host printer. The parameters *x!*,*y!* define the upper left corner of the position of the image. *hLst* is the handle of the IMAGELIST and *index&* is the selector of the image to be displayed (1=first, 2=second, etc.). If *overlay&* is non-zero, it specifies an overlay image to be added to the printed image from the image list. The parameter *style&* may be one of the following style bits:

%ILD_NORMAL	Draws the image using the background color of the image list. If the background color is the default value %CLR_NONE (defined in the Commctrl.inc file), the image is drawn transparently.
%ILD_TRANSPARENT	Draws the image transparently if there is a mask.
%ILD_MASK	Draws the mask.
%ILD_BLEND25	If there is a mask, the image is drawn blending 25% with the system highlight color.
%ILD_BLEND50	If there is a mask, the image is drawn blending 50% with the system highlight color.

See also XPRINT ATTACH, IMAGELIST

XPRINT LINE statement

XPRINT LINE statement

Purpose Draw a line on a host printer page.

Syntax `XPRINT LINE [STEP] [(x1!, y1!)] - [STEP] (x2!, y2!)[, rgbColor&]`

Remarks The line is drawn from the first point, up to, but not including the second point. Coordinate points are specified in pixels, unless optional world coordinates have been defined with an XPRINT SCALE statement. Line width can be set using XPRINT WIDTH. If line width is set to 1 (the default), the line style can be set with XPRINT STYLE. If executed without a host printer attached, error 57 is generated.

Windows graphic conventions consider the final x2 and y2 coordinates to be exclusive. Therefore, by default, the final pixel is not drawn unless Overlap Mode is enabled. See

	XPRINT SET OVERLAP for details.
x1!, *y1!*	Optional values which define the starting point of the line. If this optional first point is omitted, the line begins at the last point referenced ( ) in a preceding statement. If the first STEP option is included, the *x1!* and *y1!* starting coordinates are relative to the last point referenced (POS) on the host printer page.
x2!, *y2!*	The ending point of the line. If the second STEP option is included, the *x2!* and *y2!* ending coordinates are relative to the starting coordinates.
rgbColor&	Optional RGB color value for the line. If *rgbColor&* is omitted (or -1), the line color defaults to the current foreground color for the host printer page.
See also	Built In RGB Color Equates, XPRINT ARC, XPRINT ATTACH, XPRINT BOX, XPRINT COLOR, XPRINT ELLIPSE, XPRINT PIE, XPRINT POLYGON, XPRINT POLYLINE, XPRINT SET MIX, XPRINT SET OVERLAP, XPRINT STYLE, XPRINT WIDTH

Example

```
' Draw a triangle. Note that, since LINE draws up to,
' but not including the second point, one extra point
' must be added when STEP is used.
XPRINT LINE (10, 10) - (10, 100)  ' left side
XPRINT LINE STEP - (101, 100)     ' base line
XPRINT LINE STEP - (10, 10)       ' back to top
```

XPRINT PIE statement

XPRINT PIE statement

Purpose Draw a pie section on a host printer page.

Syntax **XPRINT PIE (*x1!*, *y1!*) - (*x2!*, *y2!*), *arcStart!*, *arcEnd!* [, [*rgbColor&*] [, [*fillcolor&*] [, [*fillstyle&*]]]]**

Remarks A pie section is an arc, with a line drawn from each end point to the center of the circle or ellipse. To specify a pie section, you would first define the full circle or ellipse of which it is a part, and then specify the points on the ellipse where the arc starts and stops.

The full circle or ellipse is defined by its bounding rectangle, which is defined as the smallest rectangle which can be drawn around the circle or ellipse. For example, if the circle is centered at position (400,400), with a radius of 100 pixels, the upper left corner (x1,y1) of the bounding rectangle is (300,300), and the lower right corner (x2,y2) is (500,500).

The start point and end point of the arc are specified by their angle, which must be given in radians. A complete circle or ellipse is 2*pi radians. On a 12-hour clock-face, the values 0 and 2*pi both refer to the position of 3 o'clock, while the value 1*pi refers to the position of 9 o'clock. Other positions are specified by a radian value relative to these. In PowerBASIC, arcs are always drawn counter-clockwise from the starting point to the ending point.

Prior to any

operations, a host printer must first be selected with XPRINT ATTACH. The coordinate points are specified in pixels (or world coordinates, if those were chosen with XPRINT SCALE). Line width can be set using XPRINT WIDTH. If line width is set to 1 (the default), the line style can be set with XPRINT STYLE. Because of the nature of a pie section, XPRINT PIE neither uses, nor updates, (last point referenced). If executed without a host printer attached, error 57 is generated.

x1!, *y1!*	The upper left corner of the bounding rectangle of the full circle or ellipse.
x2!, *y2!*	The lower right corner of the bounding rectangle of the full circle or ellipse.
ArcStart!	The starting angle of the arc, in radians, from 0 to 2*pi.

ArcEnd!	The ending angle of the arc, in radians, from 0 to 2*pi radians. Note that arcs are always drawn counter-clockwise from *arcStart!* to *arcEnd!*. Compared with a 12-hour clock-face, 0 or 2*pi radians is at 3 o'clock, and 1*pi radians is at 9 o'clock.
rgbColor&	Optional RGB color of the pie edge. If omitted (or -1), the edge color defaults to the current foreground color for the host printer page.
fillcolor&	Optional RGB color of the pie interior. If *fillcolor&* is omitted (or -2), the interior of the pie is not filled, allowing the background to show through. If *fillcolor&* is -1, the interior is painted with the same color as the edge. Otherwise, *fillcolor&* specifies the RGB color to be used.
fillstyle&	Optional fill style (pattern) to be used. If *fillstyle&* is omitted, the default fill style is solid (0). If a hatch pattern is chosen (1 to 6), the foreground color is specified by the *fillcolor&*, while the background is specified by the default background color for the host printer page. The optional *fillstyle&* may be:

0	Solid (default)
1	Horizontal Lines
2	Vertical Lines
3	Upward Diagonal Lines
4	Downward Diagonal Lines
5	Crossed Lines
6	Diagonal Crossed Lines

See also Built In RGB Color Equates, XPRINT ARC, XPRINT ATTACH, XPRINT BOX, XPRINT COLOR, XPRINT ELLIPSE, XPRINT LINE, XPRINT STYLE, XPRINT WIDTH

Example

```
' A full circle is 2*pi radians (100%).
' To show a 25% Pie, use the formula 0.25 * 2 * pi.
' The following divides a full circle into four 25% parts, each
' with its own colors, each slightly separated from the others.
' Note: 0 is at 3 o'clock, then it builds counter-clockwise.
LOCAL Pi2 AS DOUBLE
Pi2 = ATN(1)* 8  ' 2 * Pi can be useful here
XPRINT PIE (10, 9)-(110, 109), 0, Pi2 * 0.25, %BLUE, %LTGRAY, 3
XPRINT PIE (9, 9)-(109, 109), Pi2 * 0.25, Pi2 * 0.50, %RED, %LTGRAY, 4
XPRINT PIE (9, 10)-(109, 110), Pi2 * 0.5,  Pi2 * 0.75, RGB(0,127,0), %
LTGRAY, 3
XPRINT PIE (10, 10)-(110, 110), Pi2 * 0.75, 0, %GRAY, %LTGRAY, 4
```

XPRINT POLYGON statement

XPRINT POLYGON statement

Purpose Draw a polygon on a host printer page.

Syntax **XPRINT POLYGON points [, [*rgbColor&*] [, [*fillcolor&*] [, [*fillstyle&*] [, *fillmode&*]]]]**

Remarks The coordinate points are specified in pixels, unless optional world coordinates have been defined with an XPRINT SCALE statement. Line width can be set using XPRINT WIDTH. If line width is set to 1 (the default), the line style can be set with XPRINT STYLE. XPRINT POLYGON neither uses, nor updates, the last point referenced (

). If executed without a host printer attached, error 57 is generated.

points User-defined type that defines the number of vertices and the location of each. There must be at least two, and no more than 1024 vertices. The first member is a long integer point count, followed directly by the appropriate number of single precision floats to specify the actual coordinates. Floating point coordinates are required, because of the possibility of their use as world coordinates with XPRINT SCALE. You can use a type with a scalar list, like this:

```
TYPE PolyPoints
  count as long
```

```
  x1 as single
  y1 as single
  x2 as single
  y2 as single
  x3 as single
  y3 as single
END TYPE
Or, you can create an array using point types, like this:
TYPE PolyPoint
  x as single
  y as single
END TYPE

TYPE PolyArray
  count as long
  xy(1 TO 3) as PolyPoint
END TYPE
```

rgbColor& Optional RGB color of the polygon edge. If omitted (or -1), the edge color defaults to the current foreground color for the host printer page.

fillcolor& Optional RGB color of the polygon interior. If *fillcolor&* is omitted (or -2), the interior of the ellipse is not filled, allowing the background to show through. If *fillcolor&* is -1, the interior is painted with the same color as the edge. Otherwise, *fillcolor&* specifies the RGB color to be used.

fillstyle& Optional fill style (pattern) to be used. If *fillstyle&* is omitted, the default fill style is solid (0). If a hatch pattern is chosen (1 to 6), the foreground color is specified by the *fillcolor&*, while the background is specified by the default background color for the host printer page. The optional *fillstyle&* may be:

0	Solid (default)
1	Horizontal Lines
2	Vertical Lines
3	Upward Diagonal Lines
4	Downward Diagonal Lines
5	Crossed Lines
6	Diagonal Crossed Lines

fillmode& If *fillmode&* is missing (or zero), the winding mode is selected. This fills any region with a non-zero winding value. If *fillmode&* is non-zero, the alternate mode is selected. This fills the area between odd-numbered and even-numbered polygon sides on each scan line. That is, it fills the area between the first side and the second side, between the third side and fourth side, etc.

See also Built In RGB Color Equates, XPRINT ARC, XPRINT ATTACH, XPRINT BOX, XPRINT COLOR, XPRINT ELLIPSE, XPRINT LINE, XPRINT POLYLINE

XPRINT POLYLINE statement

XPRINT POLYLINE statement

Purpose Draw a series of connected lines on a host printer page.

Syntax **XPRINT POLYLINE *points [, rgbColor&*]**

Remarks The coordinate points are specified in pixels, unless optional world coordinates have been defined with an XPRINT SCALE statement. Line width can be set using XPRINT WIDTH. If line width is set to 1 (the default), the line style can be set with XPRINT STYLE. XPRINT POLYLINE neither uses, nor updates, the last point referenced (

). If executed without a host printer attached, error 57 is generated.

Windows graphic conventions consider the final x2 and y2 coordinates to be exclusive. Therefore, by default, the final pixel is not drawn unless Overlap Mode is enabled. See

XPRINT SET OVERLAP for details.

points User-defined type that defines the number of vertices and the location of each. There must be at least two, and no more than 1024 vertices. The first member is a long integer point count, followed directly by the appropriate number of single precision floats to specify the actual coordinates. Floating point coordinates are required, because of the possibility of their use as world coordinates with SCALE. You can use a type with a scalar list, like this:

```
TYPE PolyPoints
  count as long
  x1 as single
  y1 as single
  x2 as single
  y2 as single
  x3 as single
  y3 as single
END TYPE
Or, you can create an array using point types, like this:
TYPE PolyPoint
  x as single
  y as single
END TYPE

TYPE PolyArray
  count as long
  xy(1 TO 3) as PolyPoint
END TYPE
```

rgbColor& Optional RGB color of the polygon edge. If omitted (or -1), the edge color defaults to the current foreground color for the host printer page.

See also Built In RGB Color Equates, XPRINT ARC, XPRINT ATTACH, XPRINT BOX, XPRINT COLOR, XPRINT ELLIPSE, XPRINT LINE, XPRINT POLYGON, XPRINT SET OVERLAP, XPRINT STYLE, XPRINT WIDTH

XPRINT PREVIEW statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT PREVIEW statement New!

Purpose Display a replica of a printed document on the screen.

Syntax
```
XPRINT PREVIEW hWin, ID [, CALL xxx]
XPRINT PREVIEW CLOSE
```

Remarks Print Preview is a powerful concept which should be considered in most application programs which provide printed reports. Briefly, the idea involves displaying a printed report on the screen before it is committed to printing on paper.

XPRINT PREVIEW allows you to redirect output from

statements to a graphic , control, or window so that it may be displayed on the screen. When XPRINT PREVIEW CLOSE is executed, XPRINT output reverts back to the host printer so that a repeat of the XPRINT code is now sent to the printer for completion of the printed report.

XPRINT PREVIEW selects the graphic target, and should be executed directly after the printer is selected with XPRINT ATTACH. The target is identified by the handle and ID given when it was created. You can optionally specify a callback function which is called upon every execution of an XPRINT FORMFEED or XPRINT CLOSE.

XPRINT PREVIEW must be executed immediately after XPRINT ATTACH or an error 98 "XPrint Preview Error" will be generated at run time. No XPRINT statements (other than the XPRINT$ function) may be executed between XPRINT ATTACH and XPRINT PREVIEW.

If you include the CallBack option, the callback procedure must be a simple SUB with no parameters and no return value. It is called automatically by the XPRINT engine at the completion of each preview page (upon execution of XPRINT FORMFEED or XPRINT PREVIEW CLOSE. This Sub can perform all sorts of housekeeping help, such as copying the preview bitmap for separate storage, counting pages in the report, or most anything else needed by your program. Copying the bitmap is important in multi-page reports as XPRINT FORMFEED erases the graphic target for preview of the next page.

See also XPRINT ATTACH, XPRINT CLOSE, XPRINT FORMFEED

XPRINT PRINT statement

XPRINT PRINT statement IMPROVED

Purpose Output text to be printed on the selected printer.

Syntax

```
XPRINT PRINT [EXPRLIST] [POS(n)] [SPC(n)] [TAB(n)] [,] [;]...
XPRINT [EXPRLIST] [POS(n)] [SPC(n)] [TAB(n)] [,] [;]...
```

Remarks Prior to any XPRINT operations, you should be certain that a printer has been selected with XPRINT ATTACH. The text foreground and background color are set with XPRINT COLOR. Text which extends beyond the bounds of the page is clipped. The size of the text to be printed can be determined in advance with XPRINT TEXT SIZE, and formatted to fit a particular field with XPRINT SPLIT. Drawing begins at the last point referenced by another statement, or the point specified by XPRINT SET POS. The upper left corner of the text is positioned at the POS.

XPRINT PRINT has the following parts, which may occur in any order and quantity, within a single statement:

EXPRLIST and/or expression(s) which are written to the page. A semicolon can be used as separator between multiple expressions in the same statement. Upon completion, the POS is moved to the left margin of the next line.

POS(*n*) An optional function used to set the POS to the horizontal page unit (pixel, scaled unit, etc.) specified by the numeric argument, Multiple uses of the POS function is permitted in a single statement. The vertical position is unchanged.

SPC(*n*) An optional function used to insert *n* spaces into the printed output. Multiple uses of SPC is permitted in a single statement. Values of *n* less than 1 are ignored.

TAB(*n*) An optional function used to tab to the *n*th column before printing the next expression. Multiple use of TAB is permitted in a single statement. Since TAB references columns, rather than pixels, it can give unpredictable results when used with a variable width font. It is best used with a fixed width font.

[;|,] Special characters that determine the position of the next text item printed. A semicolon (;) means the next text item is printed immediately; a comma (,) means the next text item is printed at the start of the next print zone. Print zones begin every 14 columns.

If the final argument is a semicolon or comma, the POS is maintained at the current location, rather than the default action of moving to the start of the next line. For example:

```
XPRINT PRINT "Hello";
XPRINT PRINT " world!";
```

...produces the contiguous result "Hello world!"

If you omit all arguments, XPRINT PRINT just moves the POS to the left margin of the next line. Any control codes, such as Carriage Return, Line-Feed, and Backspace are not interpreted. They will display as symbols in the current selected font.

USING$ is a separate function, which may be included in the *ExprList*. See the USING$() function for more information.

It is not possible to print a User-Defined Type (UDT), a Variant, an object variable, or an entire array. Individual member values must be extracted with the appropriate function before they can be displayed.

See also FONT NEW, LPRINT, XPRINT ATTACH, XPRINT CELL, XPRINT CHR SIZE, XPRINT COLOR, XPRINT CLOSE, XPRINT SET FONT, XPRINT GET POS, XPRINT SET POS, XPRINT SET WORDWRAP, XPRINT SET WRAP, XPRINT SPLIT, XPRINT TEXT SIZE

Example

```
' Typical XPRINT printing strategy
ERRCLEAR
XPRINT ATTACH DEFAULT  ' Use default printer
IF ERR = 0 AND LEN(XPRINT$) > 0 THEN
  XPRINT "This is your printer talking"
  XPRINT FORMFEED      ' Issue a formfeed
  XPRINT CLOSE         ' detach the printer
END IF
```

XPRINT RENDER statement

XPRINT RENDER statement

Purpose Render an image on a host printer page.

Syntax **XPRINT RENDER *BmpName$*, (*x1!*, *y1!*)-(*x2!*, *y2!*)**

Remarks Renders an image (bitmap or icon), loaded from a resource or a disk file, to a host printer page. The parameter *BmpName$* contains the name of the image to be loaded. If *BmpName$* contains a period, it is presumed to be the name of a disk file. Otherwise, an attempt is made to load it from the program's resource data; if not found, it is then presumed to be a disk file. The parameters x1!,y1! define the upper left corner of the destination rectangle, while x2!,y2! define the lower right corner of that rectangle. If the destination rectangle is larger or smaller than the original, the image is stretched or condensed to the requested size. If XPRINT RENDER is unsuccessful, an appropriate error is generated.

The following code will retrieve the natural size of an image in a bitmap file, in pixels:

```
nFile& = FREEFILE
OPEN "myimage.bmp" FOR BINARY AS nFile&
GET #nFile&, 19, nWidth&
GET #nFile&, 23, nHeight&
CLOSE nFile&
```

See also XPRINT ATTACH, XPRINT COPY, XPRINT STRETCH, XPRINT SET STRETCHMODE

XPRINT SCALE statement

XPRINT SCALE statement

Purpose Define a custom world coordinate system for a host printer page.

Syntax

```
XPRINT SCALE (x1!, y1!)-(x2!, y2!)
XPRINT SCALE PIXELS
```

Remarks XPRINT SCALE lets you define your own world coordinate system for all subsequent statements. World coordinates may be values, with the only requirement that *x1!* not equal *x2!*, and *y1!* not equal *y2!*. If either pair are equal, an error 5 is generated. The custom coordinates remain with the printer page until XPRINT SCALE is repeated, or the host printer is detached. If executed without a host printer attached, error 57 is generated.

If *x2!* is greater than *x1!*, coordinates grow larger as they move to the right. Otherwise, they grow larger as they move to the left.

If *y2!* is greater than *y1!*, coordinates grow larger as they move downward. Otherwise, they grow larger as they move upward.

By default, the position *x2!*/*y2!* translates to the first pixel which is outside of the client area, and therefore not drawn. However, if OVERLAP MODE is enabled by XPRINT SET OVERLAP, x2!/y2! translates to the final pixel in the client area and is drawn.

XPRINT SCALE PIXELS sets or resets the coordinate system to pixel coordinates.

See also XPRINT ATTACH, XPRINT GET SCALE, XPRINT SET OVERLAP statement

Example

```
' Attach the default Windows printer
XPRINT ATTACH DEFAULT

' Retrieve the client size (printable area) of the printer page
XPRINT GET CLIENT TO ncWidth!, ncHeight!

' Retrieve the resolution (points per inch) of the attached printer
XPRINT GET PPI TO x&, y&

' Width in inches of the printable area
ncWidth!  = ncWidth!/x&

' Height in inches of the printable area
ncHeight! = ncHeight!/y&

' Set the scale to inches, for American letter-size paper
' in portrait mode. This is the equivalent to 8.5x11 minus the margins.
XPRINT SCALE (0,0)-(ncWidth!,ncHeight!)
```

XPRINT SET CLIP statement

XPRINT SET CLIP statement New!

Purpose Establishes margins around the outer edges of the print page.

Syntax

```
XPRINT SET CLIP LeftMargin!, TopMargin!, RightMargin!, BottomMargin!
```

Remarks This statement establishes margins on any or all sides of the selected printer. All subsequent

operations are "clipped" on these boundaries, so that no additional text or graphics are written in these protected areas.

Each of the 4 parameters is specified in the PAGE UNITS currently in effect. However, as this changes the target space available to you, the page units are immediately set to pixels/points. The upper left corner of the clip area is now addressed as point (0,0), while the right and bottom limits are reduced by the size of the margins. If you would prefer to use new Scaled Page Units for this revised clip area, you must executes a new XPRINT SCALE.

XPRINT SET CLIP is particularly useful for displaying text, where enclosing "white space" improves the appearance a good deal.

You can disable a clip area by executing GRAPHIC SET CLIP 0,0,0,0.

See also XPRINT GET CANVAS, XPRINT GET CLIENT, XPRINT GET SCALE, XPRINT SCALE

XPRINT SET COLLATE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT SET COLLATE statement

Purpose Change the XPRINT collate status.

Syntax `XPRINT SET COLLATE numrexp`

Remarks XPRINT allows you to set the collate status, if the printer driver supports both multiple copies and collate capability. XPRINT SET COLLATE enables or disables collating, depending upon the value of the *numrexp* (1=true 0=false). The following equates are predefined in the compiler to symbolically represent the possible status:

```
%DMCOLLATE_FALSE        = 0
%DMCOLLATE_TRUE         = 1
```

If the printer does not support collating, or other values are used, error 5 is generated. If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET COLLATE

XPRINT SET COLORMODE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT SET COLORMODE statement

Purpose Changes the XPRINT colormode status.

Syntax **`XPRINT SET COLORMODE`** ***`numrexp`***

Remarks XPRINT allows you to set the color or monochrome print mode if the printer driver supports it. XPRINT SET COLORMODE expects a

expression which evaluates to one of the following listed values. The following equates are predefined in the compiler to symbolically represent the possible status:

```
%DMCOLOR_MONOCHROME    = 1
%DMCOLOR_COLOR         = 2
```

If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET COLORMODE

XPRINT SET COPIES statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT SET COPIES statement

Purpose Change the XPRINT copy count.

Syntax **`XPRINT SET COPIES`** ***`numrexp`***

Remarks XPRINT SET COPIES allows you to set the number of copies to be automatically printed, if it is supported by the printer driver. The default value is one (1). If multiple copies are not supported by the printer driver, or the count requested is greater than that supported by the printer driver, error 5 is generated. If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET COPIES

XPRINT SET DUPLEX statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT SET DUPLEX statement

Purpose Change the XPRINT duplex status.

Syntax **`XPRINT SET DUPLEX`** ***`numrexp`***

Remarks XPRINT allows you to set the duplex status, if the printer supports printing on both sides of a page. XPRINT SET DUPLEX changes the mode to that specified by the *numrexp*. The following equates are predefined in the compiler to symbolically represent the possible duplex status:

```
%DMDUP_SIMPLEX        = 1    (single sided printing)
%DMDUP_VERTICAL       = 2    (page flipped on the vertical edge)
%DMDUP_HORIZONTAL     = 3    (page flipped on the horizontal edge)
```

If the printer does not support duplex printing, error 5 is generated. If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET DUPLEX

XPRINT SET FONT statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT SET FONT statement IMPROVED

Purpose Select a font for the XPRINT statement.

Syntax `XPRINT SET FONT FontHndl&`

fonthndl& The numeric handle returned by the FONT NEW statement.

Remarks The font specified by *FontHndl&* is selected to be used by

statements. This is the most efficient way to change fonts and their general appearance (size, style, etc.). If you specify a *FontHndl&* of zero, the font is changed back to the original default font chosen by PowerBASIC.

You can predefine virtually any number of fonts and attributes by executing FONT NEW statements for each of them. That makes them ready for immediate use when selected by XPRINT SET FONT.

Prior to any XPRINT operations, a specific printer must first be selected with XPRINT ATTACH. If no specific font is selected, the default font is Courier New with no style attributes.

See also FONT NEW, XPRINT, XPRINT ATTACH, XPRINT CHR SIZE, XPRINT TEXT SIZE

XPRINT SET MIX statement

XPRINT SET MIX statement

Purpose Set the color mix mode for a host printer page.

Syntax `XPRINT SET MIX mode&`

Remarks Prior to any graphical operations, a host printer must first be selected with XPRINT ATTACH. There are 16 mix modes available to use for mixing the drawing color with the color that already exists at the drawing location. The default mix mode is 13, %mix_CopySrc. The mix mode equates are predefined in PowerBASIC.

%MIX_BLACKNESS	Pixel is always 0 (black).
%MIX_NOTMERGESRC	Pixel is the inverse of the MergeSrc color.
%MIX_MASKNOTSRC	Pixel is a combination of the colors common to both the pixel and the inverse of the source.
%MIX_NOTCOPYSRC	Pixel is the inverse of the pen color.
%MIX_MASKSRCNOT	Pixel is a combination of the colors common to both the source and the inverse of the pixel.
%MIX_NOT	Pixel is the inverse of the pixel color.
%MIX_XORSRC	Pixel is a combination of the colors in the source and in the pixel, but not in both.
%MIX_NOTMASKSRC	Pixel is the inverse of the MaskSrc color.
%MIX_MASKSRC	Pixel is a combination of the colors common to both the source and the pixel.
%MIX_NOTXORSRC	Pixel is the inverse of the XorSrc color.
%MIX_NOP	Pixel remains unchanged.
%MIX_MERGENOTSRC	Pixel is a combination of the source color and the inverse of the pixel color.
%MIX_COPYSRC	Pixel is the source color (default).
%MIX_MERGESRCNOT	Pixel is a combination of the source color and the inverse of the pixel color.
%MIX_MERGESRC	Pixel is a combination of the source color and the pixel color.
%MIX_WHITENESS	Pixel is always 1 (white).

See also XPRINT ATTACH, XPRINT GET MIX

XPRINT SET ORIENTATION statement

XPRINT SET ORIENTATION statement

Purpose Set the paper orientation for a host printer page.

Syntax `XPRINT SET ORIENTATION orent&`

Remarks XPRINT SET ORIENTATION sets the orientation of the paper in the host printer. The value 1 indicates portrait mode, while 2 indicates landscape mode. If a host printer is not attached, or does not support setting the orientation, error 57 is generated.

See also FONT NEW, XPRINT ATTACH, XPRINT GET ORIENTATION, XPRINT SET FONT

XPRINT SET OVERLAP statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT SET OVERLAP statement New!

Purpose Enables or disables XPRINT Overlap Mode.

Syntax `XPRINT SET OVERLAP [NumrExpr&]`

Remarks XPRINT SET OVERLAP enables or disables overlap mode for the host printer which is currently attached to the XPRINT stream. It has no effect on any other XPRINT target. If *NumrExpr&* is true (non-zero), overlap mode is enabled. If false (zero), overlap mode is disabled. If *NumrExpr&* is missing, the default is to enable Overlap Mode.

With Overlap Mode, you can control how PowerBASIC treats XPRINT operations which involve a bounding rectangle (RECT structure) in their definition. Windows maintains unique conventions for a RECT. The bottom and right coordinates of a RECT are exclusive. In other words, the pixels at the bottom and right edges lie immediately outside the rectangle. They are ignored. For example:

```
XPRINT BOX (0,0) - (50,50)
```

In this case, a box is drawn from 0,0 to 49,49. The final pixels at the bottom and right edge are simply not drawn. However, if Overlap Mode is enabled, the box is drawn from 0,0 to 50,50.

The Overlap Mode affects all XPRINT functions which take a bounding rectangle as a parameter. This includes XPRINT SCALE, XPRINT BOX, XPRINT ELLIPSE, XPRINT LINE, XPRINT POLYLINE, etc.

See also XPRINT BOX, XPRINT ELLIPSE, XPRINT GET OVERLAP, XPRINT LINE, XPRINT POLYLINE, XPRINT SCALE

XPRINT SET PAGES statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT SET PAGES statement New!

Purpose Sets the XPRINT page number limits for this print job.

Syntax **XPRINT SET PAGES *FromPage&, ToPage&***

Remarks You may elect to limit a particular print job to a subset of the total number of pages. This can be accomplished under program control by executing XPRINT SET PAGES, or the user can make the appropriate choice in the Print Dialog which is displayed when XPRINT ATTACH is executed with the CHOOSE option. When the pages are limited in this way, PowerBASIC handles all the details of print suppression for you.

Normally, XPRINT pages are numbered from one. The parameter *FromPage&* specifies the first page of the full report which will be printed, while *ToPage&* specifies the last page.

If XPRINT SET PAGES is executed without a host printer attached, an error 57 is generated.

See also XPRINT ATTACH, XPRINT GET PAGES, XPRINT SET COPIES

XPRINT SET PAPER statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT SET PAPER statement

Purpose Sets a new paper size/type.

Syntax `XPRINT SET PAPER papertype&`

Remarks XPRINT SET PAPER changes the paper style for the host printer to that designated by *papertype&*. The paper style is identified by an

value given in the expression *papertype&*. The following equates are predefined in the compiler, and represent the most common paper styles:

```
%DMPAPER_LETTER    =  1      Letter    8.5   x 11    inches
%DMPAPER_TABLOID   =  3      Tabloid   11    x 17    inches
%DMPAPER_LEDGER    =  4      Ledger    17    x 11    inches
%DMPAPER_LEGAL     =  5      Legal     8.5   x 14    inches
%DMPAPER_STATEMENT =  6      Statement 5.5   x 8.5   inches
%DMPAPER_EXECUTIVE =  7      Executive 7.25  x 10.5  inches
%DMPAPER_A3        =  8      A3        297   x 420   mm
%DMPAPER_A4        =  9      A4        210   x 297   mm
%DMPAPER_A5        = 11      A5        148   x 210   mm
%DMPAPER_B4        = 12      B4        250   x 354   mm
%DMPAPER_B5        = 13      B5        182   x 257   mm
%DMPAPER_FOLIO     = 14      Folio     8.5   x 13    inches
%DMPAPER_QUARTO    = 15      Quarto    215   x 275   mm
%DMPAPER_10X14     = 16      10x14     10    x 14    inches
%DMPAPER_11X17     = 17      11x17     11    x 17    inches
%DMPAPER_NOTE      = 18      Note      8.5   x 11    inches
%DMPAPER_ENV_9     = 19      9 Envlp   3.875 x 8.875 inches
%DMPAPER_ENV_10    = 20      10 Envlp  4.125 x 9.5   inches
```

Other paper style codes may be defined by Windows or printer suppliers. You can use XPRINT GET PAPERS to obtain a list of all the paper styles supported by the attached host printer.

If the printer does not support the paper style specified, error 5 is generated. If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET PAPER, XPRINT GET PAPERS

XPRINT SET PIXEL statement

XPRINT SET PIXEL statement

Purpose Set the color of a pixel on a host printer page.

Syntax `XPRINT SET PIXEL [STEP] (x!, y!) [, rgbColor&]`

Remarks XPRINT SET PIXEL draws a single pixel on the host printer page. The optional color parameter is an RGB value; if not included, the color defaults to the current foreground color for the host printer. If the STEP option is included, the *x!* and *y!* coordinates are relative to the last point referenced (

). The coordinate points are specified in pixels, unless world coordinates were set with an XPRINT SCALE statement. If no host printer is attached, error 57 is generated.

See also Built In RGB Color Equates, XPRINT ATTACH, XPRINT COLOR, XPRINT GET PIXEL

XPRINT SET POS statement

XPRINT SET POS statement

Purpose Set the last point referenced (POS) by an statement.

Syntax `XPRINT SET POS [STEP] (x!, y!)`

Remarks XPRINT SET POS allows you to set the last point referenced (POS) by XPRINT statements. If the STEP option is included, the *x!* and *y!* coordinates are relative to the prior POS. The coordinate points are specified in pixels (or world coordinates, if those were defined with an XPRINT SCALE statement). If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET POS

XPRINT SET QUALITY statement

XPRINT SET QUALITY statement

Purpose Set the print quality for a host printer.

Syntax `XPRINT SET QUALITY qual&`

Remarks XPRINT SET QUALITY sets the print quality setting for the host printer. The value 1 is draft mode, 2 is low resolution, 3 is medium resolution, and 4 is high resolution. It should be noted that some printers only allow higher resolutions to be set from the printer dialog (in XPRINT ATTACH CHOOSE). If no host printer is attached, or the printer does not support print quality settings, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET QUALITY

XPRINT SET STRETCHMODE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT SET STRETCHMODE statement New!

Purpose Sets the default bitmap stretching mode for the current DC.

Syntax `XPRINT SET STRETCHMODE ModeExpr`

Remarks There are several operations in PowerBASIC which involve stretching or condensing images on bitmaps, most notably XPRINT STRETCH. As individual pixels must be added or removed, there is a good chance that the quality of the image will be degraded. However, if you describe the nature of the image by defining a StretchMode, you can substantially enhance the appearance.

The default StretchMode is maintained individually for each DC. You can set the default mode with this statement, or retrieve it with XPRINT GET STRETCHMODE. Of course, you can also override the default StretchMode when you execute one of the affected statements.

The 4 stretch mode equates are predefined in PowerBASIC.

%BLACKONWHITE	1	This is the default Windows stretch mode, and is most appropriate for monochrome bitmaps, or those with blocks of color. Performs a boolean OR of eliminated and existing pixels. It preserves black pixels at the expense of white pixels.
%WHITEONBLACK	2	Performs a boolean OR of eliminated and existing pixels. It preserves white pixels at the expense of black pixels.
%COLORONCOLOR	3	Deletes eliminated lines of pixels without trying to preserve their information.
%HALFTONE	4	This provides the highest quality for complex color bitmaps. The average color of the destination pixel block is kept approximately the same as the source pixel block.

See also XPRINT COPY, XPRINT GET STRETCHMODE, XPRINT RENDER, XPRINT STRETCH

XPRINT SET TRAY statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT SET TRAY statement

Purpose Sets a new active printer tray.

Syntax **XPRINT SET TRAY *numrexp***

Remarks XPRINT SET TRAY changes the active paper tray on the host printer to that specified by *numrexp*. The following equates are predefined in the compiler, and represent the most common paper trays:

```
%DMBIN_UPPER         = 1
%DMBIN_LOWER         = 2
%DMBIN_MIDDLE        = 3
%DMBIN_MANUAL        = 4
%DMBIN_ENVELOPE      = 5
%DMBIN_ENVMANUAL     = 6
%DMBIN_AUTO          = 7
%DMBIN_TRACTOR       = 8
%DMBIN_SMALLFMT      = 9
%DMBIN_LARGEFMT      = 10
%DMBIN_LARGECAPACITY = 11
%DMBIN_CASSETTE      = 14
```

```
%DMBIN_FORMSOURCE    = 15
```

Other tray codes may be defined by Windows or printer suppliers, so your program should be written to consider that possibility. You can use XPRINT GET TRAYS to obtain a list of all the paper trays supported by the attached host printer.

If the printer does not support the tray change requested, error 5 is generated. If executed without a host printer attached, error 57 is generated.

See also XPRINT ATTACH, XPRINT GET TRAY, XPRINT GET TRAYS

XPRINT SET WORDWRAP statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

XPRINT SET WORDWRAP statement New!

Purpose Enables or disables XPRINT WordWrap Mode.

Syntax `XPRINT SET WORDWRAP [NumrExpr&]`

Remarks XPRINT SET WORDWRAP enables or disables WordWrap mode for the host printer which is currently attached to the XPRINT stream. It has no effect on any other printer. If *NumrExpr&* is true (non-zero), WordWrap mode is enabled. If false (zero), WordWrap mode is disabled. If *NumrExpr&* is missing, the default is to enable WordWrap Mode.

With WordWrap Mode, you can control how PowerBASIC prints text on an XPRINT page when it reaches the end of a line. Since a host printer operates on a full page basis, the default is to ignore text which is printed past the end of the line.

When WordWrap mode is enabled, it affects only XPRINT PRINT operations. If XPRINT PRINT attempts to display a word beyond the end of a row, the entire word is automatically wrapped to the first column of the next row.

Example

XPRINT SPLIT statement New!

Purpose Splits a

into two parts for printing with XPRINT.

Syntax `XPRINT SPLIT [WORD] MainStr, Part1Len TO Part1Var, Part2Var`

Remarks Generally speaking, XPRINT SPLIT allows you to determine how much text will fit on a line (or a line section), so you don't overrun the end. This is critical with variable-width fonts. Since these text characters have different widths, you cannot rely on a simple character count.

XPRINT SPLIT separates the *MainStr* string expression into two parts, which are then assigned to the two string variables specified by *Part1Var* and *Part2Var*. The

expression *Part1Len* specifies the maximum width of the print field, using page units (pixels/points, scaled units). After completion of XPRINT SPLIT, the *Part1Var* will contain those characters which can be safely printed in the print field. The *Part2Var* will contain the remaining characters, which might be printed on following lines.

Since this operation creates a "line break" not contemplated in the original text, you may have to modify the results in order to obtain the best appearance. For example, it's usually best to remove any leading spaces from *Part2Var* before printing it.

WORD If the WORD option is included, PowerBASIC guarantees that *Part1* will not end on a partial word. This may require that *Part1Len* is adjusted to a smaller value. In that case, *Part2Var* would be assigned these characters to compensate.

XPRINT STRETCH statement

XPRINT STRETCH statement IMPROVED

Purpose Copy and resize a

to the XPRINT page.

Syntax `XPRINT STRETCH hBmp, ID, (x1,y1)-(x2,y2) TO (x3,y3)-(x4,y4) [,Mix, Stretch]`
`XPRINT STRETCH PAGE hBmp, ID [, Mix, Stretch]`

Remarks You can copy a complete bitmap, or a portion of it, to the XPRINT page, while resizing it to a larger or sm variable *hBmp* specifies the handle of the source bitmap or window. The parameter *ID* is the control ident with CONTROL ADD GRAPHIC. *ID* must be zero (0) for a GRAPHIC WINDOW or a

. The destination of the stretch operation is always the attached XPRINT page. The bitmap is auto destination parameters. You must use care that your parameters are valid for the specified bitmaps, undefined.

The second form, XPRINT STRETCH PAGE, is a shortcut for copying a complete bitmap to the clip or cli page. The image is automatically stretched or condensed to fit the target appropriately.

Mix If the Mix parameter is included, it is one of the values in the following table. If not specified, a default of presumed. There are 16 mix modes available to use for mixing drawing colors with the colors which alre drawing location. The mix mode equates are predefined in PowerBASIC.

%mix_Blackness	Pixel is always 0 (black).
%mix_NotMergeSrc	Pixel is the inverse of the MergeSrc color.
%mix_MaskNotSrc	Pixel is a combination of the colors common to both the pixel and the invers
%mix_NotCopySrc	Pixel is the inverse of the pen color.
%mix_MaskSrcNot	Pixel is a combination of the colors common to both the source and the inve
%mix_Not	Pixel is the inverse of the pixel color.
%mix_XorSrc	Pixel is a combination of the colors in the source and in the pixel, but not in
%mix_NotMaskSrc	Pixel is the inverse of the MaskSrc color.
%mix_MaskSrc	Pixel is a combination of the colors common to both the source and the pix
%mix_NotXorSrc	Pixel is the inverse of the XorSrc color.
%mix_Nop	Pixel remains unchanged.
%mix_MergeNotSrc	Pixel is a combination of the source color and the inverse of the pixel color.
%mix_CopySrc	Pixel is the source color (default).
%mix_MergeSrcNot	Pixel is a combination of the source color and the inverse of the pixel color.
%mix_MergeSrc	Pixel is a combination of the source color and the pixel color.
%mix_Whiteness	Pixel is always 1 (white).

Stretch If the Stretch parameter is included, it is one of the values in the following table. If not included, or it is th mode is unchanged. An appropriate choice of stretch mode can substantially enhance the quality of bitm size. The stretch mode equates are predefined in PowerBASIC.

%BLACKONWHITE	1	This is the default Windows stretch mode, and is most appropriate or those with blocks of color. Performs a boolean OR of eliminated preserves black pixels at the expense of white pixels.
%WHITEONBLACK	2	Performs a boolean OR of eliminated and existing pixels. It preserv expense of black pixels.
%COLORONCOLOR	3	Deletes eliminated lines of pixels without trying to preserve their info
%HALFTONE	4	This provides the highest quality for complex color bitmaps. The av destination pixel block is kept approximately the same as the sourc

XPRINT STYLE statement

XPRINT STYLE statement

Purpose Set the line style to be used by various statements.

Syntax `XPRINT STYLE linestyle&`

Remarks XPRINT STYLE determines the line style which will be used when drawing various graphical objects, while the width value is set to 1. When the width value is greater than one, Windows always interprets the style as 0 (solid).

Available line styles are:

0	Solid (default)
1	Dash
2	Dot
3	DashDot

4 DashDotDot

See also XPRINT ARC, XPRINT ATTACH, XPRINT BOX, XPRINT ELLIPSE, XPRINT LINE, XPRINT PIE, XPRINT WIDTH

Example

```
' Draw a square box with blue, dotted lines
XPRINT WIDTH 1
XPRINT STYLE 2
XPRINT BOX (10, 10) - (110, 110), 0, %BLUE
```

XPRINT TEXT SIZE statement

XPRINT TEXT SIZE statement IMPROVED

Purpose Calculate the size of text to be printed on a host printer.

Syntax

```
XPRINT TEXT SIZE txt$ To nWidth!, nHeight!
Function Form:
WidthVar!  = XPRINT(TEXT.SIZE.X, txt$)
HeightVar! = XPRINT(TEXT.SIZE.Y, txt$)
```

Remarks This statement calculates the total size of the printed text, based upon the current font for the host printer. The sizes returned are specified in Page Units.

This allows you to easily calculate the appropriate print position, particularly when using a proportional font. If this statement is executed without a host printer attached, error 57 is generated.

See also XPRINT CELL SIZE, XPRINT CHR SIZE, XPRINT SET FONT

Example

```
FUNCTION PBMAIN
  ' The following example draws the text both horizontally
  ' and vertically centered on the host printer page

  LOCAL x, y, w, h, w2, h2 AS LONG
  LOCAL sText AS STRING
  sText = "PowerBASIC"

  XPRINT ATTACH "Lexmark C750"
  XPRINT COLOR %BLUE, -2  ' blue text, clear background
  XPRINT FONT "Times New Roman", 18, 3  ' 18p, bold, italic

  XPRINT GET CLIENT TO w, h  ' get client size
  XPRINT TEXT SIZE sText TO w2, h2      ' get text size
  x = (w-w2) / 2                        ' centered x-pos
  y = (h-h2) / 2                        ' centered y-pos

  XPRINT SET POS (x, y)                 ' set position
  XPRINT sText                          ' draw the text
  XPRINT CLOSE
END FUNCTION
```

XPRINT WIDTH statement

XPRINT WIDTH statement

Purpose Set the graphic line width to be used by various statements..

Syntax

```
XPRINT WIDTH ncPixels&
```

Remarks XPRINT WIDTH determines the line width which will be used when drawing various graphical objects. The default width is 1 pixel. The width is always specified in pixels, regardless of any XPRINT SCALE option. When the width is set to a value greater than 1, XPRINT STYLE parameters are always interpreted as 0 (solid).

See also XPRINT ARC, XPRINT ATTACH, XPRINT BOX, XPRINT ELLIPSE, XPRINT LINE, XPRINT PIE, XPRINT STYLE

Example

```
FUNCTION PBMAIN
  XPRINT ATTACH "Lexmark C750"
  ' Draw a square box with thick, red lines
  XPRINT WIDTH 10
  XPRINT BOX (10, 10) - (110, 110), 0, %RED
  XPRINT CLOSE
END FUNCTION
```

License Agreement

LICENSE AGREEMENT IN PLAIN ENGLISH (see below for legal version)

This Agreement is between you and PowerBasic Tools, LLC ("PowerBASIC"). Your use of the Software is governed by this Agreement.

PowerBASIC legally owns the Software, tools, and related products and documentation associated with PowerBasic, and it's protected by copyright and trademark.

The Software is licensed to you; you do not own it.

The license is good for one person using one computer at a time. You can create your own products using this Software without paying us anything extra, but you cannot distribute the PowerBASIC IDE, Compiler, or PB/Forms.

If you are writing a tool such as a compiler, interpreter, or programming language, you may not republish underlying PowerBASIC runtime as your own.

We warrant the physical medium of providing the Software will not have defects for 60 days. No other warranties are included, in fact, they're specifically excluded.

If you have a warranty claim, you have to let us know during the Warranty Period and we have 90 days to fix it or refund your money. Our liability will never be more than the amount you paid for the Software. That's it. No additional liability for PowerBASIC.

You agree to defend us against other parties and not hold us responsible for your actions or the products you create, even if you used PowerBASIC to create those products. This includes almost any conceivable notion of liability.

Since we're based in North Carolina, but have customers all over the world, we're going to use North Carolina law to define and decide any disagreements

.

ANY LICENSE DISPUTE WILL BE GOVERNED BY THE LEGAL VERSION OF THE POWERBASIC LICENSE AGREEMENT (BELOW).

POWERBASIC LICENSE AGREEMENT (Legal Version)

This License Agreement (the "Agreement") is an agreement between you (referred to herein as "you" or "Licensee") and PowerBasic Tools, LLC ("PowerBASIC").

The PowerBASIC compiler and licensed tools (collectively and individually, the "Software") are proprietary products of PowerBASIC and are protected by United States copyright law and international treaties.

The Software, tools, and related products and documentation and various trademarks, service marks and trade names (collectively "Intellectual Property") are the sole and exclusive property of PowerBASIC, and may be protected by copyright, trademark, trade secret and other intellectual property laws. Any use of PowerBASIC's Intellectual Property without PowerBASIC's express written consent is prohibited.

The Software is licensed, not sold, only on the condition Licensee agrees to and complies with the terms

and conditions of this Agreement. PowerBASIC grants to Licensee a non-exclusive, non-transferable, non-

sublicensable, limited license to use the Software and any associated manuals and/or documentation, subject to Licensee's strict compliance with this Agreement and PowerBASIC's Terms of Use and Privacy Policy.

This license is valid for use by one person only, whose name will be registered with PowerBASIC on one computer at a time. The Software may be transferred from one computer to another as long as there is no possibility of it being used on more than one computer at the same time. By written request to PowerBASIC, you may specify a change of licensed user if the new user is your employee or family member. If the Software is used on a network, one licensed copy of the Software is required for each person who uses the Software. If the licensed Software is a compiler, you may distribute the programs you create royalty free. This license grants Licensee no right to sub-license or in any way provide the Software to a third party. You may not distribute the licensed compiler. If the Software includes one or more runtime modules, you may reproduce and distribute the runtime modules royalty free, provided they are distributed only in conjunction with, and as part of your software program, and provided that the program incorporating the modules bears the copyright notice which appears on the PowerBASIC label or PowerBASIC.com website. The runtime modules are those files that are required to execute your software program, and which are specifically designated as "runtime modules" in the accompanying PowerBASIC documentation. Your use of any of the demonstration or sample programs provided with the Software are governed by, and subject to, the notices and restrictions of the respective author or copyright holder. Except as stated above, you may not resell, transfer ownership, barter, donate, rent, lease, lend, or share the Software to/with another person or entity. You agree to use commercially reasonable efforts to safeguard the Software against infringement, misappropriation, theft, misuse or unauthorized access.

Additional Restrictions

You may use the licensed Software to create and maintain any form of target computer program for your own use. If you publish any target computer program, freeware or commercial, which is a tool such as an interpreter, DLL or programmer's library, etc., you may not export a wrapper subroutine/function for any individual PowerBASIC command which republishes that command as your own and allows that command to be used by anyone that does not own a PowerBASIC license.

Limited Warranty; Limitation of Liability

PowerBASIC warrants that the physical disks and physical documentation are free of defects in workmanship and materials for a period of sixty (60) days from the date of purchase (the "Warranty Period"). If the disks or documentation are found to be defective within the Warranty Period, PowerBASIC will replace the defective items at no cost to you. PowerBASIC's entire liability under this warranty is limited to replacement or refund of the Software and documentation and shall not, under any circumstances, include any other damages.

During the Warranty Period, Licensee shall promptly notify PowerBASIC in writing of any claimed deficiency and provide information sufficient to permit PowerBASIC to validate the deficiency. If a deficiency exists which breaches the warranty, PowerBASIC shall, at its sole discretion and within ninety (90) days: (i)

correct the deficiency; or (ii) with PowerBASIC’s prior written authorization and upon Licensee’s de-

installation of the Software and return of all copies of the Software to PowerBASIC, refund any license fee paid to PowerBASIC, whereupon this Agreement shall terminate. Under no circumstances will PowerBASIC’s liability exceed amounts paid by the Licensee for use of the Software.

THE REMEDIES SET FORTH ABOVE ARE LICENSEE’S SOLE AND EXCLUSIVE REMEDIES FOR BREACH OF THE LIMITED WARRANTY CONTAINED IN THIS AGREEMENT.

EXCEPT FOR THE LIMITED WARRANTY SET FORTH ABOVE, THE SOFTWARE IS PROVIDED TO LICENSEE "AS IS" AND WITH ALL FAULTS AND DEFECTS WITHOUT WARRANTY OF ANY KIND. TO THE MAXIMUM EXTENT PERMITTED UNDER APPLICABLE LAW, POWERBASIC, ITS AFFILIATES, AND/OR THEIR SERVICE PROVIDERS, SUPPLIERS, EMPLOYEES, AGENTS, OFFICERS, OR DIRECTORS EXPRESSLY DISCLAIM ALL WARRANTIES, WHETHER EXPRESS, IMPLIED, STATUTORY, OR OTHERWISE, WITH RESPECT TO THE SOFTWARE AND DOCUMENTATION, INCLUDING ALL IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, TITLE, NON-INFRINGEMENT, AND WARRANTIES THAT MAY ARISE OUT OF COURSE OF DEALING, COURSE OF PERFORMANCE, USAGE, OR TRADE PRACTICE. WITHOUT LIMITATION TO THE FOREGOING, POWERBASIC, ITS AFFILIATES, AND/OR THEIR SERVICE PROVIDERS, SUPPLIERS, EMPLOYEES, AGENTS, OFFICERS, OR DIRECTORS PROVIDE NO WARRANTY OR UNDERTAKING, AND MAKE NO REPRESENTATION OF ANY KIND THAT THE LICENSED SOFTWARE WILL MEET THE LICENSEE'S REQUIREMENTS, ACHIEVE ANY INTENDED RESULTS, BE COMPATIBLE, OR WORK WITH ANY OTHER SOFTWARE, APPLICATIONS, SYSTEMS, OR SERVICES, OPERATE WITHOUT INTERRUPTION,

MEET ANY PERFORMANCE OR RELIABILITY STANDARDS OR BE ERROR FREE, OR THAT ANY ERRORS OR DEFECTS CAN OR WILL BE CORRECTED.

IN NO EVENT WILL POWERBASIC, ITS AFFILIATES, AND/OR THEIR SERVICE PROVIDERS, SUPPLIERS, EMPLOYEES, AGENTS, OFFICERS, OR DIRECTORS BE LIABLE TO LICENSEE OR ANY THIRD PARTY FOR ANY USE, INTERRUPTION, DELAY, OR INABILITY TO USE THE SOFTWARE; LOST REVENUES OR PROFITS; DELAYS, INTERRUPTION, OR LOSS OF SERVICES, BUSINESS, OR GOODWILL; LOSS OR CORRUPTION OF DATA; LOSS RESULTING FROM SYSTEM OR SYSTEM SERVICE FAILURE, MALFUNCTION, OR SHUTDOWN; FAILURE TO ACCURATELY TRANSFER, READ, OR TRANSMIT INFORMATION; FAILURE TO UPDATE OR PROVIDE CORRECT INFORMATION; SYSTEM INCOMPATIBILITY OR PROVISION OF INCORRECT COMPATIBILITY INFORMATION; BREACHES IN SYSTEM SECURITY OR UNAUTHORIZED ACCESS TO CONFIDENTIAL INFORMATION; OR FOR ANY INDIRECT, PUNITIVE, EXEMPLARY, INCIDENTAL, SPECIAL, CONSEQUENTIAL, OR ANY OTHER DAMAGES, WHETHER ARISING OUT OF OR IN CONNECTION WITH THIS AGREEMENT, BREACH OF CONTRACT, TORT (INCLUDING NEGLIGENCE), STRICT LIABILITY, OR OTHERWISE, REGARDLESS OF WHETHER SUCH DAMAGES WERE FORESEEABLE AND WHETHER OR NOT POWERBASIC WAS ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

IN NO EVENT WILL THE AGGREGATE LIABILITY OF POWERBASIC, ITS AFFILIATES, AND/OR THEIR SERVICE PROVIDERS, SUPPLIERS, EMPLOYEES, AGENTS, OFFICERS, OR DIRECTORS, UNDER ANY LEGAL OR EQUITABLE THEORY, INCLUDING BREACH OF CONTRACT, TORT (INCLUDING NEGLIGENCE), STRICT LIABILITY, OR OTHERWISE, EXCEED THE TOTAL AMOUNT PAID TO POWERBASIC FOR THE SOFTWARE THAT IS THE SUBJECT OF THE CLAIM.

Indemnification of PowerBASIC

LICENSEE HEREBY AGREES TO INDEMNIFY, DEFEND, AND HOLD POWERBASIC, ITS AFFILIATES, AND THEIR SERVICE PROVIDERS, SUPPLIERS, EMPLOYEES, AGENTS, OFFICERS, AND DIRECTORS, HARMLESS FROM AND AGAINST ANY AND ALL LIABILITIES, LOSSES, COSTS, EXPENSE, DAMAGES, AND DEFICIENCIES, INCLUDING, WITHOUT LIMITATION, COURT COSTS AND REASONABLE ATTORNEY FEES, WHICH DIRECTLY OR INDIRECTLY ARISE OUT OF, RESULT FROM OR RELATE TO (I) ANY AND ALL LIABILITIES, OBLIGATIONS, OR CLAIMS, WHETHER ACCRUED, ABSOLUTE, CONTINGENT, OR OTHERWISE, WHICH HAVE AS A BASIS THE OPERATION OF LICENSEE, ANY AND ALL ACCOUNTS PAYABLE OF LICENSEE, AND ANY AND ALL TAXES LEVIED OR INCURRED, WHETHER PAYABLE TO A FEDERAL, STATE, LOCAL OR OTHER GOVERNMENTAL AUTHORITY; (II) ANY AND ALL LOSSES, CLAIMS, CAUSES OF ACTION, LIABILITIES, COSTS, EXPENSES, DAMAGES OR DEFICIENCIES DUE TO ANY BREACH BY LICENSEE OF ANY OF ITS REPRESENTATIONS, WARRANTIES, OR COVENANTS CONTAINED IN THIS AGREEMENT; (III) ALL ACTIONS, SUITS, PROCEEDINGS, DEMANDS, ASSESSMENTS, JUDGMENT COSTS AND EXPENSES, INCLUDING THE COST AND EXPENSE OF SUCCESSFUL COLLECTION FROM LICENSEE OR ITS LEGAL REPRESENTATIVE, SUCCESSORS, OR ASSIGNS OF ANY AMOUNT DUE POWERBASIC HEREUNDER OR RESULTING THEREFROM; (IV) ANY HARMFUL SOFTWARE TRANSMITTED BY LICENSEE OR ON BEHALF OF LICENSEE; AND (V) UNAUTHORIZED ACCESS TO ANY PERSONALLY IDENTIFIABLE OR CONFIDENTIAL DATA ATTRIBUTABLE TO THE ACTS OR INACTION OR OMISSIONS OF THE LICENSEE; AND (VI) ANY CLAIM BY A THIRD PARTY RELATING TO LICENSEE’S USE OF THE SOFTWARE OR THE RESULTS THEREOF. The obligations set forth in this section shall survive the termination or expiration of this Agreement.

Governing Law

This Agreement shall be construed, interpreted, and governed by the laws of the State of North Carolina, USA, and any action hereunder shall be brought only in North Carolina.

Export Regulation

The Software may be subject to US export control laws, including the US Export Administration Act and its associated regulations. Licensee shall not, directly or indirectly, export, re-export, or release the Software to, or make the Software accessible from, any jurisdiction or country to which export, re-export, or release is prohibited by law, rule, or regulation. Licensee shall comply with all applicable laws, regulations, and rules, and complete all required undertakings (including obtaining any necessary export license or other governmental approval), prior to exporting, re-exporting, releasing, or otherwise making the Software available outside the US.

US Government Rights

The Software and documentation is "commercial computer software", as such term is defined in 48 C.F.R. §2.101, 48 C.F.R. §252.227-7014(a)(1) or otherwise. Accordingly, if Licensee is the US Government or any contractor therefor, Licensee shall receive only those rights with respect to the Software and documentation as are granted to all other Licensees, in accordance with (a) 48 C.F.R. §227.7201 through 48 C.F.R. §227.7204, with respect to the Department of Defense and their contractors, or (b) 48 C.F.R. §12.212, with respect to all other US Government Licensees and their contractors. Use, duplication, or disclosure by the US Government of the Software and documentation shall be subject to the restricted rights under 48 C.F.R.

§252.227-7013 and similar clauses of the Federal Acquisition Regulations applicable to commercial

computer software.

Miscellaneous

This Agreement, together with our Terms of Use and Privacy Policy, constitutes the entire agreement between you and PowerBASIC. If any provision is found invalid or unenforceable, the balance of this Agreement shall remain valid and enforceable. No failure to exercise, and no delay in exercising, on the part of either party, any right or any power hereunder shall operate as a waiver thereof, nor shall any single or partial exercise of any right or power hereunder preclude further exercise of that or any other right hereunder. This Agreement is for the sole benefit of the parties hereto and their respective successors and permitted assigns and nothing herein, express or implied, is intended to or shall confer on any other person any legal or equitable right, benefit, or remedy of any nature whatsoever under or by reason of this Agreement. All rights not specifically granted herein are reserved by PowerBASIC.
