You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as

either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved

sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

`REMOVE <12> (`*`PowerKey`*` AS WString)`

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`REPLACE <13> (`*`PowerKey`*` AS WString, `*`PowerItem`*` AS Variant)`

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`SORT <14> (`*`Flags`*` AS Long)`

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

`ADD <3> (`*`PowerItem`*` AS Variant)`

The *PowerItem* variant is added to the end of the LinkListCollection.

`CLEAR <4>`

All *PowerItems* are removed from the LinkListCollection.

`COUNT <5> AS Long`

The number of data items currently contained in the LinkListCollection is returned to the caller.

`FIRST <1> AS Long`

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

`INDEX <6> (`*`Index`*` AS Long) AS Long`

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

`IndexVar& = ObjectVar.INDEX(0)`

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

`INSERT <7> (`*`Index`*` AS Long, `*`PowerItem`*` AS Variant)`

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If

the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may

be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position

number, or sequentially in ascending or descending sequence.

Syntax *The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is

successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection

A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax

The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should

be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the

caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**

<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose

A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax *The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

IndexVar& = ObjectVar.INDEX(0)

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection

A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

```
IndexVar& = ObjectVar.INDEX(0)
```

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
```

```
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`REPLACE <12> (Index AS Long, PowerItem AS Variant)`

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

`CLEAR <1>`

All *PowerItems* are removed from the StackCollection.

`COUNT <2> AS Long`

The number of data items currently contained in the StackCollection is returned to the caller.

`POP <3> AS Variant`

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`PUSH <4> (PowerItem AS Variant)`

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection

A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax

The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

`CLEAR <1>`

All *PowerItems* are removed from the QueueCollection.

`COUNT <2> AS Long`

The number of data items currently contained in the QueueCollection is returned to the caller.

`DEQUEUE <3> AS Variant`

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`ENQUEUE <4> (PowerItem AS Variant)`

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

Example

COLLECTION Object Group New!

Purpose

A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax *The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

IndexVar& = ObjectVar.INDEX(0)

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax *The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

`COUNT <2> AS Long`

The number of data items currently contained in the StackCollection is returned to the caller.

`POP <3> AS Variant`

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`PUSH <4> (PowerItem AS Variant)`

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

`CLEAR <1>`

All *PowerItems* are removed from the QueueCollection.

`COUNT <2> AS Long`

The number of data items currently contained in the QueueCollection is returned to the caller.

`DEQUEUE <3> AS Variant`

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`ENQUEUE <4> (PowerItem AS Variant)`

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`SORT <14> (Flags AS Long)`

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

`ADD <3> (PowerItem AS Variant)`

The *PowerItem* variant is added to the end of the LinkListCollection.

`CLEAR <4>`

All *PowerItems* are removed from the LinkListCollection.

`COUNT <5> AS Long`

The number of data items currently contained in the LinkListCollection is returned to the caller.

`FIRST <1> AS Long`

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

`INDEX <6> (Index AS Long) AS Long`

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

`IndexVar& = ObjectVar.INDEX(0)`

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

`INSERT <7> (Index AS Long, PowerItem AS Variant)`

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

`ITEM <8> (Index AS Long) AS Variant`

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`LAST <9> AS Long`

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax *The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

`CLEAR <1>`

All *PowerItems* are removed from the QueueCollection.

`COUNT <2> AS Long`

The number of data items currently contained in the QueueCollection is returned to the caller.

`DEQUEUE <3> AS Variant`

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`ENQUEUE <4> (PowerItem AS Variant)`

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax *The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose

A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL

interface).

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

IndexVar& = *ObjectVar*.INDEX(0)

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax *The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns % S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

`PREVIOUS <10> AS Variant`

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

`REMOVE <11> (Index AS Long)`

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`REPLACE <12> (Index AS Long, PowerItem AS Variant)`

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

`CLEAR <1>`

All *PowerItems* are removed from the StackCollection.

`COUNT <2> AS Long`

The number of data items currently contained in the StackCollection is returned to the caller.

`POP <3> AS Variant`

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`PUSH <4> (PowerItem AS Variant)`

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection

A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax

The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

IMAGELIST ADD BITMAP statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

IMAGELIST statement

Purpose Create and manage an IMAGELIST object to use with other functions.

Syntax

```
IMAGELIST ADD BITMAP hLst, hBmp [,hMsk] [TO dataValue&]
IMAGELIST ADD BITMAP hLst, Bmp$ [,Msk$] [TO dataValue&]
IMAGELIST ADD ICON hLst, hIcn [TO dataValue&]
IMAGELIST ADD ICON hLst, Icn$ [TO dataValue&]
IMAGELIST ADD MASKED hLst, hBmp, rgbColor& [TO dataValue&]
IMAGELIST ADD MASKED hLst, Bmp$, rgbColor& [TO dataValue&]
IMAGELIST GET COUNT hLst TO dataValue&
IMAGELIST KILL hLst
IMAGELIST NEW BITMAP|ICON nWidth&, nHeight&, depth&, initial& TO hLst
IMAGELIST SET OVERLAY hLst, image&, overlay&
```

hBmp Handle of a Bitmap.

hIcn Handle of an Icon.

hLst Handle of the IMAGELIST.

hMsk Handle of a Mask.

dataValue& A long integer variable to which result data is assigned.

rgbColor& A RGB color used in the bitmap to specify transparent pixels.

Remarks An IMAGELIST is a structure which contains any number of graphical images, either bitmaps or icons, but not a mixture. All of the images are automatically converted to the type, size, and color depth specified when the IMAGELIST is created. A bitmap (file type *.BMP) is a single color image, while an icon (file type *.ICO) supports transparency by including both a color bitmap and a mask bitmap. The mask bitmap is a monochrome image (one bit per pixel), where each "set" bit describes a pixel which remains transparent. The IMAGELIST structure can best be described as a set, or array, of images. You can retrieve the images individually by index number, or pass the entire IMAGELIST to a control which requires it (LISTVIEW, etc.).

An empty ImageList is first created with IMAGELIST NEW. Images are then added with IMAGELIST ADD, until the structure is complete. If you add an image which is wider than the size specified by *nWidth&*, the image is separated into multiple bitmaps, each of which is added in sequence. When an IMAGELIST is attached to a control like LISTVIEW, it is usually destroyed automatically when the control is destroyed. Consult the control documentation for that information. If not, you must explicitly destroy it with IMAGELIST KILL.

IMAGELIST ADD BITMAP *hLst*, *hBmp* [,*hMsk*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with

). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD BITMAP *hLst*, *Bmp$* [,*Msk$*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a name

(*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *hIcn* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a handle (*hIcn*), so it must have been loaded into memory (e.g. with the WinApi LoadIcon. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *Icn$* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a name string (*Icn$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the icon name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *hBmp*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with GRAPHIC BITMAP). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *Bmp$*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a name string (*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST GET COUNT *hLst* TO *dataValue&*

The number of images in the IMAGELIST is retrieved, and assigned to the long integer variable specified by *dataValue&*.

IMAGELIST KILL *hLst*

The IMAGELIST specified by *hLst* is destroyed. All allocated memory and resources are released.

IMAGELIST NEW BITMAP|ICON *nWidth&*, *nHeight&*, *depth&*, *initial&* TO *hLst*

A new ImageList structure is created. If you specify BITMAP, each image you add will be stored as a single bitmap. If you specify ICON, each image you add will be stored as two bitmaps in order to support transparent areas. The parameters *nWidth&* and *nHeight&* specify the size of each image in pixels. The *depth&* parameter specifies the color depth in bits per pixel (4,8,16,24,32). A depth of 4 offers 16 colors, 8 offers 256 colors, etc. The *initial&* parameter specifies the initial size of the ImageList. While it can grow beyond this number, it is most efficient to allocate space accurately at the time of creation. The variable *hLst* receives the handle of the newly created ImageList, or zero if the operation failed.

IMAGELIST SET OVERLAY *hLst*, *image&*, *overlay&*

The image specified by the index number *image&* is declared to be an overlay image. The *overlay&* parameter must be in the range of 1 to 15, and it is used later to retrieve and/or specify this particular overlay image.

Example

IMAGELIST statement

Purpose Create and manage an IMAGELIST object to use with other functions.

Syntax

```
IMAGELIST ADD BITMAP hLst, hBmp [,hMsk] [TO dataValue&]
IMAGELIST ADD BITMAP hLst, Bmp$ [,Msk$] [TO dataValue&]
IMAGELIST ADD ICON hLst, hIcn [TO dataValue&]
IMAGELIST ADD ICON hLst, Icn$ [TO dataValue&]
IMAGELIST ADD MASKED hLst, hBmp, rgbColor& [TO dataValue&]
IMAGELIST ADD MASKED hLst, Bmp$, rgbColor& [TO dataValue&]
IMAGELIST GET COUNT hLst TO dataValue&
IMAGELIST KILL hLst
IMAGELIST NEW BITMAP|ICON nWidth&, nHeight&, depth&, initial& TO hLst
IMAGELIST SET OVERLAY hLst, image&, overlay&
```

hBmp Handle of a Bitmap.

hIcn Handle of an Icon.

hLst Handle of the IMAGELIST.

hMsk Handle of a Mask.

dataValue& A long integer variable to which result data is assigned.

rgbColor& A RGB color used in the bitmap to specify transparent pixels.

Remarks An IMAGELIST is a structure which contains any number of graphical images, either bitmaps or icons, but not a mixture. All of the images are automatically converted to the type, size, and color depth specified when the IMAGELIST is created. A bitmap (file type *.BMP) is a single color image, while an icon (file type *.ICO) supports transparency by including both a color bitmap and a mask bitmap. The mask bitmap is a monochrome image (one bit per pixel), where each "set" bit describes a pixel which remains transparent. The IMAGELIST structure can best be described as a set, or array, of images. You can retrieve the images individually by index number, or pass the entire IMAGELIST to a control which requires it (LISTVIEW, etc.).

An empty ImageList is first created with IMAGELIST NEW. Images are then added with IMAGELIST ADD, until the structure is complete. If you add an image which is wider than the size specified by *nWidth&*, the image is separated into multiple bitmaps, each of which is added in sequence. When an IMAGELIST is attached to a control like LISTVIEW, it is usually destroyed automatically when the control is destroyed. Consult the control documentation for that information. If not, you must explicitly destroy it with IMAGELIST KILL.

IMAGELIST ADD BITMAP *hLst*, *hBmp* [,*hMsk*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with

). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD BITMAP *hLst*, *Bmp$* [,*Msk$*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a name

(*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign

("#12345"). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *hIcn* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a handle (*hIcn*), so it must have been loaded into memory (e.g. with the WinApi LoadIcon. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *Icn$* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a name string (*Icn$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the icon name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *hBmp*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with GRAPHIC BITMAP). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *Bmp$*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a name string (*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST GET COUNT *hLst* TO *dataValue&*

The number of images in the IMAGELIST is retrieved, and assigned to the long integer variable specified by *dataValue&*.

IMAGELIST KILL *hLst*

The IMAGELIST specified by *hLst* is destroyed. All allocated memory and resources are released.

IMAGELIST NEW BITMAP|ICON *nWidth&*, *nHeight&*, *depth&*, *initial&* TO *hLst*

A new ImageList structure is created. If you specify BITMAP, each image you add will be stored as a single bitmap. If you specify ICON, each image you add will be stored as two bitmaps in order to support transparent areas. The parameters *nWidth&* and *nHeight&* specify the size of each image in pixels. The *depth&* parameter specifies the color depth in bits per pixel (4,8,16,24,32). A depth of 4 offers 16 colors, 8 offers 256 colors, etc. The *initial&* parameter specifies the initial size of the ImageList. While it can grow beyond this number, it is most efficient to allocate space accurately at the time of creation. The variable *hLst* receives the handle of the newly created ImageList, or zero if the operation failed.

IMAGELIST SET OVERLAY *hLst*, *image&*, *overlay&*

The image specified by the index number *image&* is declared to be an overlay image. The *overlay&* parameter must be in the range of 1 to 15, and it is used later to retrieve and/or specify this particular overlay image.

IMAGELIST statement

Purpose Create and manage an IMAGELIST object to use with other functions.

Syntax

```
IMAGELIST ADD BITMAP hLst, hBmp [,hMsk] [TO dataValue&]
IMAGELIST ADD BITMAP hLst, Bmp$ [,Msk$] [TO dataValue&]
IMAGELIST ADD ICON hLst, hIcn [TO dataValue&]
IMAGELIST ADD ICON hLst, Icn$ [TO dataValue&]
IMAGELIST ADD MASKED hLst, hBmp, rgbColor& [TO dataValue&]
IMAGELIST ADD MASKED hLst, Bmp$, rgbColor& [TO dataValue&]
IMAGELIST GET COUNT hLst TO dataValue&
IMAGELIST KILL hLst
IMAGELIST NEW BITMAP|ICON nWidth&, nHeight&, depth&, initial& TO hLst
IMAGELIST SET OVERLAY hLst, image&, overlay&
```

hBmp Handle of a Bitmap.

hIcn Handle of an Icon.

hLst Handle of the IMAGELIST.

hMsk Handle of a Mask.

dataValue& A long integer variable to which result data is assigned.

rgbColor& A RGB color used in the bitmap to specify transparent pixels.

Remarks An IMAGELIST is a structure which contains any number of graphical images, either bitmaps or icons, but not a mixture. All of the images are automatically converted to the type, size, and color depth specified when the IMAGELIST is created. A bitmap (file type *.BMP) is a single color image, while an icon (file type *.ICO) supports transparency by including both a color bitmap and a mask bitmap. The mask bitmap is a monochrome image (one bit per pixel), where each "set" bit describes a pixel which remains transparent. The IMAGELIST structure can best be described as a set, or array, of images. You can retrieve the images individually by index number, or pass the entire IMAGELIST to a control which requires it (LISTVIEW, etc.).

An empty ImageList is first created with IMAGELIST NEW. Images are then added with IMAGELIST ADD, until the structure is complete. If you add an image which is wider than the size specified by *nWidth&*, the image is separated into multiple bitmaps, each of which is added in sequence. When an IMAGELIST is attached to a control like LISTVIEW, it is usually destroyed automatically when the control is destroyed. Consult the control documentation for that information. If not, you must explicitly destroy it with IMAGELIST KILL.

IMAGELIST ADD BITMAP *hLst*, *hBmp* [,*hMsk*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD BITMAP *hLst*, *Bmp$* [,*Msk$*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a name (*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *hIcn* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a handle (*hIcn*), so it must have been loaded into memory (e.g. with the WinApi LoadIcon. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *Icn$* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a name string (*Icn$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the icon name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *hBmp*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with GRAPHIC BITMAP). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *Bmp$*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a name string (*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST GET COUNT *hLst* TO *dataValue&*

The number of images in the IMAGELIST is retrieved, and assigned to the long integer variable specified by *dataValue&*.

IMAGELIST KILL *hLst*

The IMAGELIST specified by *hLst* is destroyed. All allocated memory and resources are released.

IMAGELIST NEW BITMAP|ICON *nWidth&*, *nHeight&*, *depth&*, *initial&* TO *hLst*

A new ImageList structure is created. If you specify BITMAP, each image you add will be stored as a single bitmap. If you specify ICON, each image you add will be stored as two bitmaps in order to support transparent areas. The parameters *nWidth&* and *nHeight&* specify the size of each image in pixels. The *depth&* parameter specifies the color depth in bits per pixel (4,8,16,24,32). A depth of 4 offers 16 colors, 8 offers 256 colors, etc. The *initial&* parameter specifies the initial size of the ImageList. While it can grow beyond this number, it is most efficient to allocate space accurately at the time of creation. The variable *hLst* receives the handle of the newly created ImageList, or zero if the operation failed.

IMAGELIST SET OVERLAY *hLst*, *image&*, *overlay&*

The image specified by the index number *image&* is declared to be an overlay image. The *overlay&* parameter must be in the range of 1 to 15, and it is used later to retrieve and/or specify this particular overlay image.

Example

IMAGELIST statement

Purpose Create and manage an IMAGELIST object to use with other functions.

Syntax

```
IMAGELIST ADD BITMAP hLst, hBmp [,hMsk] [TO dataValue&]
IMAGELIST ADD BITMAP hLst, Bmp$ [,Msk$] [TO dataValue&]
IMAGELIST ADD ICON hLst, hIcn [TO dataValue&]
IMAGELIST ADD ICON hLst, Icn$ [TO dataValue&]
IMAGELIST ADD MASKED hLst, hBmp, rgbColor& [TO dataValue&]
IMAGELIST ADD MASKED hLst, Bmp$, rgbColor& [TO dataValue&]
IMAGELIST GET COUNT hLst TO dataValue&
IMAGELIST KILL hLst
IMAGELIST NEW BITMAP|ICON nWidth&, nHeight&, depth&, initial& TO hLst
IMAGELIST SET OVERLAY hLst, image&, overlay&
```

hBmp Handle of a Bitmap.

hIcn Handle of an Icon.

hLst Handle of the IMAGELIST.

hMsk Handle of a Mask.

dataValue& A long integer variable to which result data is assigned.

rgbColor& A RGB color used in the bitmap to specify transparent pixels.

Remarks An IMAGELIST is a structure which contains any number of graphical images, either bitmaps or icons, but not a mixture. All of the images are automatically converted to the type, size, and color depth specified when the IMAGELIST is created. A bitmap (file type *.BMP) is a single color image, while an icon (file type *.ICO) supports transparency by including both a color bitmap and a mask bitmap. The mask bitmap is a monochrome image (one bit per pixel), where each "set" bit describes a pixel which remains transparent. The IMAGELIST structure can best be described as a set, or array, of images. You can retrieve the images individually by index number, or pass the entire IMAGELIST to a control which requires it (LISTVIEW, etc.).

An empty ImageList is first created with IMAGELIST NEW. Images are then added with IMAGELIST ADD, until the structure is complete. If you add an image which is wider than the size specified by *nWidth&*, the image is separated into multiple bitmaps, each of which is added in sequence. When an IMAGELIST is attached to a control like LISTVIEW, it is usually destroyed automatically when the control is destroyed. Consult the control documentation for that information. If not, you must explicitly destroy it with IMAGELIST KILL.

IMAGELIST ADD BITMAP *hLst*, *hBmp* [,*hMsk*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with

). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD BITMAP *hLst*, *Bmp$* [,*Msk$*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a name

(*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *hIcn* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a handle (*hIcn*), so it must have been loaded into memory (e.g. with the WinApi LoadIcon. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *Icn$* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a name string (*Icn$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the icon name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *hBmp*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with GRAPHIC BITMAP). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *Bmp$*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a name string (*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST GET COUNT *hLst* TO *dataValue&*

The number of images in the IMAGELIST is retrieved, and assigned to the long integer variable specified by *dataValue&*.

IMAGELIST KILL *hLst*

The IMAGELIST specified by *hLst* is destroyed. All allocated memory and resources are released.

IMAGELIST NEW BITMAP|ICON *nWidth&*, *nHeight&*, *depth&*, *initial&* TO *hLst*

A new ImageList structure is created. If you specify BITMAP, each image you add will be stored as a single bitmap. If you specify ICON, each image you add will be stored as two bitmaps in order to support transparent areas. The parameters *nWidth&* and *nHeight&* specify the size of each image in pixels. The *depth&* parameter specifies the color depth in bits per pixel (4,8,16,24,32). A depth of 4 offers 16 colors, 8 offers 256 colors, etc. The *initial&* parameter specifies the initial size of the ImageList. While it can grow beyond this number, it is most efficient to allocate space accurately at the time of creation. The variable *hLst* receives the handle of the newly created ImageList, or zero if the operation failed.

IMAGELIST SET OVERLAY *hLst*, *image&*, *overlay&*

The image specified by the index number *image&* is declared to be an overlay image. The *overlay&* parameter must be in the range of 1 to 15, and it is used later to retrieve and/or specify this particular overlay image.

IMAGELIST KILL hLst
IMAGELIST NEW BITMAP|ICON nWidth&, nHeight&, depth&, initial& TO hLst
IMAGELIST SET OVERLAY hLst, image&, overlay&
```

hBmp Handle of a Bitmap.

hIcn Handle of an Icon.

hLst Handle of the IMAGELIST.

hMsk Handle of a Mask.

dataValue& A long integer variable to which result data is assigned.

rgbColor& A RGB color used in the bitmap to specify transparent pixels.

Remarks An IMAGELIST is a structure which contains any number of graphical images, either bitmaps or icons, but not a mixture. All of the images are automatically converted to the type, size, and color depth specified when the IMAGELIST is created. A bitmap (file type *.BMP) is a single color image, while an icon (file type *.ICO) supports transparency by including both a color bitmap and a mask bitmap. The mask bitmap is a monochrome image (one bit per pixel), where each "set" bit describes a pixel which remains transparent. The IMAGELIST structure can best be described as a set, or array, of images. You can retrieve the images individually by index number, or pass the entire IMAGELIST to a control which requires it (LISTVIEW, etc.).

An empty ImageList is first created with IMAGELIST NEW. Images are then added with IMAGELIST ADD, until the structure is complete. If you add an image which is wider than the size specified by *nWidth&*, the image is separated into multiple bitmaps, each of which is added in sequence. When an IMAGELIST is attached to a control like LISTVIEW, it is usually destroyed automatically when the control is destroyed. Consult the control documentation for that information. If not, you must explicitly destroy it with IMAGELIST KILL.

IMAGELIST ADD BITMAP *hLst*, *hBmp* [,*hMsk*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with

). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD BITMAP *hLst*, *Bmp$* [,*Msk$*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a name

(*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *hIcn* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a handle (*hIcn*), so it must have been loaded into memory (e.g. with the WinApi LoadIcon. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *Icn$* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a name string (*Icn$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the icon name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *hBmp*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with

GRAPHIC BITMAP). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *Bmp$*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a name string (*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST GET COUNT *hLst* TO *dataValue&*

The number of images in the IMAGELIST is retrieved, and assigned to the long integer variable specified by *dataValue&*.

IMAGELIST KILL *hLst*

The IMAGELIST specified by *hLst* is destroyed. All allocated memory and resources are released.

IMAGELIST NEW BITMAP|ICON *nWidth&*, *nHeight&*, *depth&*, *initial&* TO *hLst*

A new ImageList structure is created. If you specify BITMAP, each image you add will be stored as a single bitmap. If you specify ICON, each image you add will be stored as two bitmaps in order to support transparent areas. The parameters *nWidth&* and *nHeight&* specify the size of each image in pixels. The *depth&* parameter specifies the color depth in bits per pixel (4,8,16,24,32). A depth of 4 offers 16 colors, 8 offers 256 colors, etc. The *initial&* parameter specifies the initial size of the ImageList. While it can grow beyond this number, it is most efficient to allocate space accurately at the time of creation. The variable *hLst* receives the handle of the newly created ImageList, or zero if the operation failed.

IMAGELIST SET OVERLAY *hLst*, *image&*, *overlay&*

The image specified by the index number *image&* is declared to be an overlay image. The *overlay&* parameter must be in the range of 1 to 15, and it is used later to retrieve and/or specify this particular overlay image.

rgbColor&	A RGB color used in the bitmap to specify transparent pixels.

Remarks

An IMAGELIST is a structure which contains any number of graphical images, either bitmaps or icons, but not a mixture. All of the images are automatically converted to the type, size, and color depth specified when the IMAGELIST is created. A bitmap (file type *.BMP) is a single color image, while an icon (file type *.ICO) supports transparency by including both a color bitmap and a mask bitmap. The mask bitmap is a monochrome image (one bit per pixel), where each "set" bit describes a pixel which remains transparent. The IMAGELIST structure can best be described as a set, or array, of images. You can retrieve the images individually by index number, or pass the entire IMAGELIST to a control which requires it (LISTVIEW, etc.).

An empty ImageList is first created with IMAGELIST NEW. Images are then added with IMAGELIST ADD, until the structure is complete. If you add an image which is wider than the size specified by *nWidth&*, the image is separated into multiple bitmaps, each of which is added in sequence. When an IMAGELIST is attached to a control like LISTVIEW, it is usually destroyed automatically when the control is destroyed. Consult the control documentation for that information. If not, you must explicitly destroy it with IMAGELIST KILL.

IMAGELIST ADD BITMAP *hLst*, *hBmp* [,*hMsk*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD BITMAP *hLst*, *Bmp$* [,*Msk$*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a name (*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *hIcn* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a handle (*hIcn*), so it must have been loaded into memory (e.g. with the WinApi LoadIcon. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *Icn$* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a name string (*Icn$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the icon name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *hBmp*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with GRAPHIC BITMAP). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *Bmp$*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a name string (*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST GET COUNT *hLst* TO *dataValue&*

The number of images in the IMAGELIST is retrieved, and assigned to the long integer variable specified by *dataValue&*.

IMAGELIST KILL *hLst*

The IMAGELIST specified by *hLst* is destroyed. All allocated memory and resources are released.

IMAGELIST NEW BITMAP|ICON *nWidth&, nHeight&, depth&, initial&* TO *hLst*

A new ImageList structure is created. If you specify BITMAP, each image you add will be stored as a single bitmap. If you specify ICON, each image you add will be stored as two bitmaps in order to support transparent areas. The parameters *nWidth&* and *nHeight&* specify the size of each image in pixels. The *depth&* parameter specifies the color depth in bits per pixel (4,8,16,24,32). A depth of 4 offers 16 colors, 8 offers 256 colors, etc. The *initial&* parameter specifies the initial size of the ImageList. While it can grow beyond this number, it is most efficient to allocate space accurately at the time of creation. The variable *hLst* receives the handle of the newly created ImageList, or zero if the operation failed.

IMAGELIST SET OVERLAY *hLst, image&, overlay&*

The image specified by the index number *image&* is declared to be an overlay image. The *overlay&* parameter must be in the range of 1 to 15, and it is used later to retrieve and/or specify this particular overlay image.

IMAGELIST ADD MASKED hLst, Bmp$, rgbColor& [TO dataValue&]
IMAGELIST GET COUNT hLst TO dataValue&
IMAGELIST KILL hLst
IMAGELIST NEW BITMAP|ICON nWidth&, nHeight&, depth&, initial& TO hLst
IMAGELIST SET OVERLAY hLst, image&, overlay&
```

hBmp Handle of a Bitmap.

hIcn Handle of an Icon.

hLst Handle of the IMAGELIST.

hMsk Handle of a Mask.

dataValue& A long integer variable to which result data is assigned.

rgbColor& A RGB color used in the bitmap to specify transparent pixels.

Remarks An IMAGELIST is a structure which contains any number of graphical images, either bitmaps or icons, but not a mixture. All of the images are automatically converted to the type, size, and color depth specified when the IMAGELIST is created. A bitmap (file type *.BMP) is a single color image, while an icon (file type *.ICO) supports transparency by including both a color bitmap and a mask bitmap. The mask bitmap is a monochrome image (one bit per pixel), where each "set" bit describes a pixel which remains transparent. The IMAGELIST structure can best be described as a set, or array, of images. You can retrieve the images individually by index number, or pass the entire IMAGELIST to a control which requires it (LISTVIEW, etc.).

An empty ImageList is first created with IMAGELIST NEW. Images are then added with IMAGELIST ADD, until the structure is complete. If you add an image which is wider than the size specified by *nWidth&*, the image is separated into multiple bitmaps, each of which is added in sequence. When an IMAGELIST is attached to a control like LISTVIEW, it is usually destroyed automatically when the control is destroyed. Consult the control documentation for that information. If not, you must explicitly destroy it with IMAGELIST KILL.

IMAGELIST ADD BITMAP *hLst*, *hBmp* [,*hMsk*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with

). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD BITMAP *hLst*, *Bmp$* [,*Msk$*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a name

(*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *hIcn* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a handle (*hIcn*), so it must have been loaded into memory (e.g. with the WinApi LoadIcon. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *Icn$* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a name string (*Icn$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the icon name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *hBmp*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with GRAPHIC BITMAP). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *Bmp$*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a name string (*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST GET COUNT *hLst* TO *dataValue&*

The number of images in the IMAGELIST is retrieved, and assigned to the long integer variable specified by *dataValue&*.

IMAGELIST KILL *hLst*

The IMAGELIST specified by *hLst* is destroyed. All allocated memory and resources are released.

IMAGELIST NEW BITMAP|ICON *nWidth&*, *nHeight&*, *depth&*, *initial&* TO *hLst*

A new ImageList structure is created. If you specify BITMAP, each image you add will be stored as a single bitmap. If you specify ICON, each image you add will be stored as two bitmaps in order to support transparent areas. The parameters *nWidth&* and *nHeight&* specify the size of each image in pixels. The *depth&* parameter specifies the color depth in bits per pixel (4,8,16,24,32). A depth of 4 offers 16 colors, 8 offers 256 colors, etc. The *initial&* parameter specifies the initial size of the ImageList. While it can grow beyond this number, it is most efficient to allocate space accurately at the time of creation. The variable *hLst* receives the handle of the newly created ImageList, or zero if the operation failed.

IMAGELIST SET OVERLAY *hLst*, *image&*, *overlay&*

The image specified by the index number *image&* is declared to be an overlay image. The *overlay&* parameter must be in the range of 1 to 15, and it is used later to retrieve and/or specify this particular overlay image.

IMAGELIST SET OVERLAY statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

IMAGELIST statement

Purpose Create and manage an IMAGELIST object to use with other functions.

Syntax

```
IMAGELIST ADD BITMAP hLst, hBmp [,hMsk] [TO dataValue&]
IMAGELIST ADD BITMAP hLst, Bmp$ [,Msk$] [TO dataValue&]
IMAGELIST ADD ICON hLst, hIcn [TO dataValue&]
IMAGELIST ADD ICON hLst, Icn$ [TO dataValue&]
IMAGELIST ADD MASKED hLst, hBmp, rgbColor& [TO dataValue&]
IMAGELIST ADD MASKED hLst, Bmp$, rgbColor& [TO dataValue&]
IMAGELIST GET COUNT hLst TO dataValue&
IMAGELIST KILL hLst
IMAGELIST NEW BITMAP|ICON nWidth&, nHeight&, depth&, initial& TO hLst
IMAGELIST SET OVERLAY hLst, image&, overlay&
```

hBmp Handle of a Bitmap.

hIcn Handle of an Icon.

hLst Handle of the IMAGELIST.

hMsk Handle of a Mask.

dataValue& A long integer variable to which result data is assigned.

rgbColor& A RGB color used in the bitmap to specify transparent pixels.

Remarks An IMAGELIST is a structure which contains any number of graphical images, either bitmaps or icons, but not a mixture. All of the images are automatically converted to the type, size, and color depth specified when the IMAGELIST is created. A bitmap (file type *.BMP) is a single color image, while an icon (file type *.ICO) supports transparency by including both a color bitmap and a mask bitmap. The mask bitmap is a monochrome image (one bit per pixel), where each "set" bit describes a pixel which remains transparent. The IMAGELIST structure can best be described as a set, or array, of images. You can retrieve the images individually by index number, or pass the entire IMAGELIST to a control which requires it (LISTVIEW, etc.).

An empty ImageList is first created with IMAGELIST NEW. Images are then added with IMAGELIST ADD, until the structure is complete. If you add an image which is wider than the size specified by *nWidth&*, the image is separated into multiple bitmaps, each of which is added in sequence. When an IMAGELIST is attached to a control like LISTVIEW, it is usually destroyed automatically when the control is destroyed. Consult the control documentation for that information. If not, you must explicitly destroy it with IMAGELIST KILL.

IMAGELIST ADD BITMAP *hLst*, *hBmp* [,*hMsk*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD BITMAP *hLst*, *Bmp$* [,*Msk$*] [TO *dataValue&*]

An image is added to the ImageList specified by *hLst*. With this syntax, the image is specified by a name

(*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the ImageList is an ICON type, a second mask bitmap is also specified by a handle (*hMsk*). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *hIcn* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a handle (*hIcn*), so it must have been loaded into memory (e.g. with the WinApi LoadIcon. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD ICON *hLst*, *Icn$* [TO *dataValue&*]

An icon is added to the ImageList specified by *hLst*. With this syntax, the icon is specified by a name string (*Icn$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the icon name is a numeric resource, it should be described with a leading pound sign ("#12345"). If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *hBmp*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a handle (*hBmp*), so it must have been loaded into memory (e.g. with GRAPHIC BITMAP). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added icon (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST ADD MASKED *hLst*, *Bmp$*, *rgbColor&* [TO *dataValue&*]

A bitmap is added to the icon ImageList specified by *hLst*. With this syntax, the bitmap is specified by a name string (*Bmp$*), which is the name of an embedded resource or a disk file. If the name string contains a period, it is presumed to be a disk file. Otherwise, an attempt is made to load it from a resource - if not found, it is then presumed to be a disk file. If the image name is a numeric resource, it should be described with a leading pound sign ("#12345"). The parameter *rgbColor&* specifies the RGB color used in the bitmap to specify transparent pixels. Each pixel of that color is changed to the color black, and a mask bitmap is created to describe the transparent pixels. If the TO clause is included, the index position of the first added bitmap (starting with 1) is assigned to the variable designated by *dataValue&*. If the operation fails, the value 0 is assigned.

IMAGELIST GET COUNT *hLst* TO *dataValue&*

The number of images in the IMAGELIST is retrieved, and assigned to the long integer variable specified by *dataValue&*.

IMAGELIST KILL *hLst*

The IMAGELIST specified by *hLst* is destroyed. All allocated memory and resources are released.

IMAGELIST NEW BITMAP|ICON *nWidth&*, *nHeight&*, *depth&*, *initial&* TO *hLst*

A new ImageList structure is created. If you specify BITMAP, each image you add will be stored as a single bitmap. If you specify ICON, each image you add will be stored as two bitmaps in order to support transparent areas. The parameters *nWidth&* and *nHeight&* specify the size of each image in pixels. The *depth&* parameter specifies the color depth in bits per pixel (4,8,16,24,32). A depth of 4 offers 16 colors, 8 offers 256 colors, etc. The *initial&* parameter specifies the initial size of the ImageList. While it can grow beyond this number, it is most efficient to allocate space accurately at the time of creation. The variable *hLst* receives the handle of the newly created ImageList, or zero if the operation failed.

IMAGELIST SET OVERLAY *hLst*, *image&*, *overlay&*

The image specified by the index number *image&* is declared to be an overlay image. The *overlay&* parameter must be in the range of 1 to 15, and it is used later to retrieve and/or specify this particular overlay image.

See also GRAPHIC BITMAP LOAD, GRAPHIC BITMAP NEW, GRAPHIC IMAGELIST, LISTVIEW, TAB SET IMAGELIST, TREEVIEW, XPRINT IMAGELIST

IMP operator

IMP operator

Purpose The IMP operator works as both a logical and a bitwise arithmetic operator.

Syntax ***p* IMP *q***

Remarks

IMP as a logical operator

The IMP operator returns FALSE (zero) if and only if its first operand is TRUE (non-zero), and its second operand is FALSE. In all other cases, it returns TRUE.

Truth table

x	y	x IMP y
T	T	T
T	F	F
F	T	T
F	F	T

Using IMP as a bitwise arithmetic operator

IMP is seldom used as a bitwise arithmetic operator, but here is a sample:

```
              1001 0111 0000 0000 = &H9700
IMP           0011 1111 1111 1111 = &H3FFF (the mask)
              0111 1111 1111 1111 = &H7FFF (result)
MSB                                 LSB (bit 0)
```

See also Arithmetic Operators, AND, EQV, ISFALSE, ISTRUE, NOT, OR, XOR

IMPORT ADDR statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

IMPORT statement New!

Purpose Load or free a library (DLL) to access an imported procedure.

Syntax
```
IMPORT ADDR  ProcName$, LibName$ TO AddrVar& [, HndlVar&]
IMPORT CLOSE LibHndl
```

Remarks In most cases, libraries are implicitly loaded automatically when you list an IMPORT or LIB option in a DECLARE statement. While that's the easiest approach, it can cause a fatal problem if the DLL is missing, or it's a version which does not include the Sub/Function you need. In that case, your program will fail at startup, and not execute at all.

IMPORT ADDR allows you to load a DLL explicitly, by name, so that you can handle a problem gracefully if the operation fails for any reason. With IMPORT ADDR, *ProcName$* specifies the name of the SUB or Function you wish to access, while *LibName$* specifies the name of the DLL and where it is located. *ProcName$* must use the correct upper/lower case for all alphabetic characters or it will fail. If the load is successful, the address of the entry point of the Sub/Function is assigned to the variable *AddrVar&*, and the handle of the DLL is assigned to the optional variable *HndlVar&*. Both of these variables must be Long Integers or DWords. If the load fails for any reason, the value zero (0) is assigned to both.

After the library (DLL) is loaded successfully, you can access the Sub/Function with CALL DWORD *AddrVar&*.

Once you are through using the library, you can release it and regain the memory used by executing IMPORT CLOSE. The expression *LibHndl* must specify the value returned in *HndlVar&* when the DLL was loaded. If you do not execute an IMPORT CLOSE, the DLL will be automatically released when your program terminates.

See also CALL DWORD, DECLARE

IMPORT CLOSE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

IMPORT statement New!

Purpose Load or free a library (DLL) to access an imported procedure.

Syntax
```
IMPORT ADDR  ProcName$, LibName$ TO AddrVar& [, HndlVar&]
IMPORT CLOSE LibHndl
```

Remarks In most cases, libraries are implicitly loaded automatically when you list an IMPORT or LIB option in a DECLARE statement. While that's the easiest approach, it can cause a fatal problem if the DLL is missing, or it's a version which does not include the Sub/Function you need. In that case, your program will fail at startup, and not execute at all.

IMPORT ADDR allows you to load a DLL explicitly, by name, so that you can handle a problem gracefully if the operation fails for any reason. With IMPORT ADDR, *ProcName$* specifies the name of the SUB or Function you wish to access, while *LibName$* specifies the name of the DLL and where it is located. *ProcName$* must use the correct upper/lower case for all alphabetic characters or it will fail. If the load is successful, the address of the entry point of the Sub/Function is assigned to the variable *AddrVar&*, and the handle of the DLL is assigned to the optional variable *HndlVar&*. Both of these variables must be Long Integers or DWords. If the load fails for any reason, the value zero (0) is assigned to both.

After the library (DLL) is loaded successfully, you can access the Sub/Function with CALL DWORD *AddrVar&*.

Once you are through using the library, you can release it and regain the memory used by executing IMPORT CLOSE. The expression *LibHndl* must specify the value returned in *HndlVar&* when the DLL was loaded. If you do not execute an IMPORT CLOSE, the DLL will be automatically released when your program terminates.

See also CALL DWORD, DECLARE

INCR statement

INCR statement

Purpose Increment a variable by 1; increment a pointer by the size of its target; or increment the target of a numeric pointer by 1.

Syntax **INCR *variable***

Remarks *variable* can be a

or a pointer variable. When INCR is used with a numeric variable, 1 is added to the numeric variable.

When INCR is used with a pointer variable itself, the value of the pointer is incremented by the size of the pointer's target.

When INCR is used on a numeric pointer's target (i.e., INCR @IntPtr) the value of the target is incremented by 1.

For example, given a pointer to an array where the pointer targets element 1000, applying INCR to the pointer would result in the pointer aiming at element 1001. The actual address held by the pointer would have risen by two, because the target of the pointer is an Integer which is two bytes wide.

Conversely, if INCR was used on the target of this Integer pointer, the value of the element itself would be incremented by 1.

See also DECR, LET

Example

```
DIM x&, LongPtr AS LONG POINTER
INCR x&
INCR LongPtr
INCR @LongPtr
```

INPUT# statement

INPUT# statement

Purpose Load variables with data from a sequential file.

Syntax **INPUT #*filenum&*, *variable_list***

Remarks *filenum&* is the file number, or variable containing a file number, given when the file was opened. *variable_list* is a comma-delimited sequence of one or more

or variables. When the INPUT# statement reads an unquoted data item from a file, it removes leading spaces. If leading spaces are significant, place quotes around the file data, either directly or by using WRITE# to save the data to disk. Please note that data to be quoted should not contain embedded quotes.

The data in the file must match the type(s) of the variable(s) defined in the INPUT# statement. The file data should be separated by commas with a carriage return at the end. The WRITE# statement is ideal for creating such files.

INPUT# also supports fixed-length and nul-terminated string variables; however, data that is longer than the string is truncated to fit into the string. Dynamic strings receive the data without truncation. UDT variables may not be used, although fixed-length and nul-terminated UDT member variables are supported.

See also LINE INPUT#, PRINT#, WRITE#

Example

```
SUB MakeFile
  ' MakeFile opens a sequential file for output.
  ' Using WRITE#, it writes lines of different
  ' data types to 'the file.
  OPEN "INPUT#.DTA" FOR OUTPUT AS #1
  StringVariable$ = "I'll be back."
  IntegerVar% = 1000
  FloatingPoint! = 30000.12
  ' Write a line of text to the sequential file.
  WRITE #1, StringVariable$, IntegerVar%, FloatingPoint!
  CLOSE #1
END SUB

SUB ReadFile
  ' This procedure opens a sequential file for
  ' input. Using INPUT# it reads lines of
  ' different data types from the file.
  OPEN "INPUT#.DTA" FOR INPUT AS #1
  RESET StringVariable$
  RESET IntegerVar%
  RESET FloatingPoint!
  ' Read a line of text from the sequential file.
  INPUT #1, StringVariable$, IntegerVar%, FloatingPoint!
  CLOSE #1
END SUB
```

INPUTBOX$ function

INPUTBOX$ function

Purpose INPUTBOX$ displays a dialog box containing a prompt. INPUTBOX$ waits for the user to enter text, and accept or cancel the dialog. INPUTBOX$ returns the contents of the text box.

Syntax ***sResult$* = INPUTBOX$(*prompt$* [[, *title$*], *default$*] [, *xpos%*, *ypos%*])**

Remarks *Prompt$* is the text prompt displayed in the Inputbox dialog.

Title$ is the caption for the Inputbox dialog and is optional.

Default$ is the default result text displayed in the edit section of the Inputbox dialog, and is optional.

xpos% and *ypos%* specify the location on the screen to display the Inputbox, in dialog units. If these are not specified, the Inputbox dialog is centered on the screen.

Restrictions The returned string value is limited to 255 characters.

See also MSGBOX function, MSGBOX statement, TXT pseudo-object

Example

```
sResult$ = INPUTBOX$("Enter your Name",, "Jane Doe")
```

INSTANCE statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

INSTANCE statement

Purpose Declare INSTANCE variables which are unique to each object.

Syntax

```
INSTANCE variable[()] [AS type] [, variable[()]]
INSTANCE variable[()] [, variable[()]] [, ...] AS type
```

Remarks INSTANCE statements are used to declare instance variables for an object. A unique set of instance variables is created for every new object, which may only be referenced from within that object. INSTANCE statements may only be placed at the beginning of a CLASS/END CLASS block, preceding all

blocks.

INSTANCE will optionally accept a list of variables, each of which are defined by the descriptor which follows it:

```
INSTANCE x as integer, y as long
```

INSTANCE will also accept a list of variables, all of which are defined by the single descriptor at the end of the list;

```
INSTANCE aaa, bbb, ccc AS INTEGER
INSTANCE vptr, aptr() AS LONG PTR
```

To declare an array as an instance variable, use an empty set of parentheses in the variable list: You can then use the DIM statement to dimension the array.

See also GLOBAL,INTERFACE (Direct), LOCAL, STATIC, THREADED, What is an object, anyway?

INSTR function

INSTR function

Purpose Search a

for the existence of a second string.

Syntax `y& = INSTR([Position&,] MainStr$, [ANY] MatchStr$)`

Remarks INSTR returns the position of *MatchStr$* within *MainStr$*. The return value is indexed to one, while zero means "not found".

Position& specifies the character position to begin the search. If *Position&* is one or greater, *MainStr$* is searched left to right. The value one starts at the first character, two the second, etc. If *Position&* is -1 or less, *MainStr$* is searched from right to left. The value -1 starts at the last character, -2 the second to last, etc. If *Position&* is not given, the default value of +1 is assumed.

```
x& = INSTR("xyz", "y")   ' returns 2
x& = INSTR("xyz", "a")   ' returns 0
a$ = "My Dog" : b$ = " "
x& = INSTR(a$, b$)       ' returns 3
```

It is important to note that in all cases, even when *Position&* is negative, the return value of INSTR() is the absolute position of the match, from left to right, starting with the first character.

ANY — If the ANY keyword is included, *MatchStr$* specifies a list of single characters. INSTR searches for each of these characters individually. As soon as any one of these characters is found, INSTR returns the position of the match.

```
x& = INSTR(-2, "efcdef", ANY "ef")   returns a result of 5
```

INSTR is case-sensitive, meaning that upper-case and lower-case letters must match exactly in *MatchStr$* and *MainStr$*.

Restrictions — Special search terms are evaluated in this sequence:

1. If *Position&* is zero, or beyond the length of *MainStr$*, the value zero is returned.
2. If *MainStr$* is null, the value zero is returned.
3. If *MatchStr$* is null, the absolute *Position&* value (default of 1) is returned.

See also — EXTRACT$, LCASE$, LEFT$, LTRIM$, MID$, RIGHT$, RTRIM$, SHRINK$, TALLY, TRIM$, UCASE$, VERIFY

Example

```
' x$ = first command-line argument, assuming spaces, commas,
' periods, and tabs are valid delimiters.
IF INSTR(COMMAND$, ANY " ,." + CHR$(9)) > 0 THEN
 x$ = "There is more than one command-line argument"
ELSE
 x$ = "There is at most one command-line argument"
END IF
```

INT function

INT function

Purpose — Convert a numeric expression to an value.

Syntax — ***y*** **= INT(*numeric_expression*)**

Remarks — INT rounds *numeric_expression* to the largest integral value that is less than or equal to *numeric_expression*.

See also — CEIL, CINT, FIX, FRAC, ROUND

Example

```
DIM X AS SINGLE, Y AS LONG
FOR X = -1.1 TO 2.1 STEP .5
  Y = INT(X)
NEXT X
```

Result

```
  X      Y
-1.1    -2
-0.6    -1
-0.1    -1
 0.4     0
```

```
0.9     0
1.4     1
1.9     1
```

INTERFACE / END INTERFACE Block (Direct)

Keyword Template

Purpose

Syntax

Remarks

See also

Example

INTERFACE / END INTERFACE Block (Direct)

Purpose

Declare a direct object interface and its member Methods/Properties.

Syntax

```
INTERFACE interfacename [$GUID] [AS EVENT] [AS HIDDEN]
  {METHOD | PROPERTY} name [([arguments])] [AS type]]
END INTERFACE
```

Remarks

The first line in an Interface Block must be an INHERIT statement. INHERIT specifies the base class or the user interface upon which this new interface is built. It defines the base methods available, the optional user methods which are available, and the calling conventions which will apply. In the current version of PowerBASIC, the following may be used:

INHERIT IUnknown

This defines a Custom Interface with only direct access to the interface methods. OBJRESULT (an hResult value) is not supported. Return values are typically passed in CPU/FPU registers, just like a user defined FUNCTION. This is the format most often used for internal objects, as it offers access to more data types than the other forms. You may substitute the word CUSTOM for IUNKNOWN, as they are synonyms.

INHERIT IAutomation

This defines an Automation Interface with only direct access to the interface methods. OBJRESULT (an hResult value) is always supported. Return values are passed as a hidden, last parameter (automatically, by PowerBASIC). Parameters and return values are limited to COM data types. A User Defined Type used as a return value or parameter will be converted to a BYVAL DWORD. This is the format most often used for COM objects which do not require access to the IDispatch interface. You may substitute the word AUTOMATION for IAUTOMATION, as they are synonyms.

INHERIT IDispatch

This defines a Dual Interface, which offers both direct access and Dispatch access to the interface methods. OBJRESULT (an hResult value) is always supported. This interface inherits from IAutomation, so the calling conventions are identical to IAutomation when used for direct access. You may substitute the word DUAL for IDISPATCH, as they are synonyms.

INHERIT *<UserClass>, <UserInterface>*

This defines an inherited user-written interface, so the new interface implements the base class IUnknown, IDispatch, etc.) and all of the Methods and Properties, as well. It's necessary to specify both the class and the interface name to be inherited, because it's possible to have multiple implementations of any particular interface.

INTERFACE / END INTERFACE statements enclose the METHOD and PROPERTY definitions which constitute a class. There are two forms of the INTERFACE / END INTERFACE block. When it appears outside of a CLASS block, it is simply a declaration of the interface, much like DECLARE statements are used for functions:

```
INTERFACE name  [$GUID]  [AS EVENT]
  INHERIT IUnknown
  METHOD MyMethod(xyz AS LONG)
  PROPERTY GET MyProp() AS STRING
END INTERFACE
```

The above form is used to declare an interface which is implemented in another .EXE or .DLL, but will be accessed here through COM services. It may also be used for added self-documentation of internal classes. If it appears within a CLASS block, it is the implementation of the Methods/Properties for the Class. The interface implementation must precisely match any prior interface declaration.

```
CLASS name  [$GUID] [AS COM]
  INTERFACE name  [$GUID] [AS HIDDEN]
    INHERIT iUnknown
    METHOD MyMethod(xyz AS LONG)
      [statements]
    END METHOD
    PROPERTY GET MyProp() AS STRING
      [statements]
    END PROPERTY
  END INTERFACE
END CLASS
```

The name and optional $GUID are supplied by the programmer to uniquely identify the interface. The first entry in every INTERFACE block must be the base class upon which it is built. Every interface must ultimately inherit from IUnknown, which is a requirement.

By default, a class is considered private, so that the methods are accessible only from within the EXE or DLL where it is defined. The AS COM attribute to the CLASS statement makes the class available externally, to virtually any process which is COM-aware.

The optional AS HIDDEN attribute to the INTERFACE statement prevents the interface from being documented when the type library is created. When marked as hidden, any and all uses of the interface are hidden, even if they appear in multiple classes.

With an internal class, the $GUID on CLASS and INTERFACE statements may be freely omitted, as PowerBASIC can readily identify them by name. With a published COM class, you should insert a specific GUID of your choice. If omitted, a random GUID will be created by the compiler, but it will change every time you compile the program. This will be difficult to synchronize with other programs which wish to identify and access your object.

The following code defines a dual interface whose methods are available for both direct access and Dispatch access. This is the form you will typically use for COM objects, since it offers the best compatibility with varied client modules.

```
INTERFACE DispatchIface
  INHERIT IDispatch
  METHOD  MethodDef()
    [statements]
  END METHOD
END INTERFACE
```

You should note that the IDispatch interface itself inherits from IUnknown, so that both interfaces are ultimately available. As an additional required base class, the IDispatch declaration is built into the PowerBASIC Compiler.

Every method and property in a dual interface needs a positive, long integer value to identify it. That integral value is known as a DispID (Dispatch ID), and it's used internally by COM services to call the correct function on a Dispatch interface. You can specify a particular DispID by enclosing it in angle brackets immediately following the Method/Property name in an Interface definition block.

```
INTERFACE DualIface
  INHERIT IDispatch
  METHOD  MethodOne <76> ()
  METHOD  MethodTwo <77> ()
END INTERFACE
```

If you don't specify a DispID, PowerBASIC will assign a random value for you. This is fine for internal objects, but may cause a failure for published COM objects, as the DispID could change each time you compile your program. It is particularly important that you specify a DispID for each Method/Property in a COM Event Interface.

Inherited User-Written Interfaces

PowerBASIC offers Implementation Inheritance of user-written interfaces. That is, an interface can inherit all of the code in the methods and properties of a selected interface. You can then add additional methods and properties to the new interface. When you inherit a user-written interface, you must specify both the class name and the interface name, since COM allows you to have multiple implementations of any particular interface.

You can override an inherited method or property by coding a replacement which is preceded by the word OVERRIDE. It's possible to one or many override procedures, but they must appear in the same sequence as the ones they replace.

```
CLASS MyClass
  INTERFACE MyFace
    INHERIT IDispatch
    METHOD aaa()
      ' code...
    END METHOD
    METHOD bbb()
      ' code...
    END METHOD
    METHOD ccc()
      ' code...
    END METHOD
    METHOD ddd()
      ' code...
    END METHOD
  END INTERFACE
END CLASS

CLASS TheClass
  INTERFACE TheFace
    INHERIT MyClass, MyFace
    OVERRIDE METHOD bbb()
      ' new code...
    END METHOD
    OVERRIDE METHOD ddd()
      ' new code...
    END METHOD
    METHOD xxx()
      ' code...
    END METHOD
  END INTERFACE
END CLASS
```

Note that in the above example, the new interface "TheFace" first inherits all four methods from "MyFace" (aaa,bbb,ccc,ddd). However, because of the OVERRIDE statements, both bbb() and ddd() are replaced by newer versions of the methods. Because of the nature of Virtual Function Tables, the OVERRIDE procedures must remain in the original sequence. That is, bbb() must precede ddd(), and both must precede any added methods, such as xxx().

Because of the nature of code replacement necessary in implementation inheritance, the interface to be inherited must always physically precede the new, child interface.

See also INTERFACE (IDBind), CLASS, INSTANCE, ISINTERFACE, LET (with Objects), ME, METHOD, MYBASE, PROPERTY, What does an Interface look like?, What is inheritance?

INTERFACE/END INTERFACE block (Dispatch)

INTERFACE/END INTERFACE block (IDBind)

Purpose Declare a dispatch interface and its member Methods/Properties for the purposes of IDBinding to a Dispatch COM interface.

Syntax

```
INTERFACE IDBIND interfacename
  MEMBER {CALL | GET | SET | LET} membername <dispid> ( [[OPTIONAL
      [IN | OUT | INOUT]] paramname <dispid> [AS type] [,...]] )
      [AS {vartype | interface}]
  [...]
END INTERFACE
```

Remarks In order to provide IDBinding services, PowerBASIC must be able to pre-construct the references to the DISPATCH COM interface members at compile-time. Without an interface definition block, only late-binding at run-time would be possible. Late-binding is less efficient than IDBinding.

You may list every Method/Property in the interface, or just the ones that are referenced in the code. They can appear in any sequence. Member names may contain (normally) reserved keywords such as INPUT or KILL, etc

The most important aspect of an interface block is that it clearly associates a *dispid* with the each Method/Property name. Named parameters in the *paramname* list also require an appropriate *dispid* value, as does any Property which returns an object to be used in a nested object reference. All *dispid* values must be enclosed in angle brackets (< and >), and may be expressed as hexadecimal or decimal numeric literals.

You can look up the *dispid* values of COM servers using an Object Browser, or by reading your object documentation. You can even insert additional information about the types and return value for your own reference, even though the compiler does not use them.

Previous versions of PowerBASIC compilers used an older style syntax of "INTERFACE DISPATCH *interfacename*" for this structure. It was updated to better reflect the nature of the description. While the older syntax will be recognized in this version, we suggest you update the word DISPATCH to IDBIND soon.

Restrictions If the compiler cannot resolve the interface name definition specified in a DIM or LET statement, a compile-time error is generated accordingly.

interfacename must not be a PowerBASIC keyword. If a keyword conflict arises, the addition of an arbitrary prefix is acceptable. For example, INTERFACE IDBIND Shell() could be changed to INTERFACE IDBIND MyShell() and PowerBASIC will still resolve the interface correctly.

Method/Property *membername* items may freely use PowerBASIC keywords without concern for conflicts with normal code syntax. For example, MEMBER CALL Open() is a valid syntax for an interface method.

See also DIM, ID Binding, INTERFACE (Direct), ISINTERFACE, LET (with Objects), Late Binding, LET (with Variants), OBJACTIVE, OBJECT, OBJPTR, OBJRESULT, PROGID$, What is an object, anyway?, What is DISPATCH?

Example

```
INTERFACE IDBIND IAPPUser
  MEMBER CALL DELETE<&H1>()
  MEMBER GET Name<&H2>() AS STRING
  MEMBER LET Name<&H2>() 'Param Type As String
  MEMBER LET Password<&H3>() 'Param Type As String
  MEMBER GET ReadOnly<&H4>() AS LONG
  MEMBER LET ReadOnly<&H4>()   'Param Type As Long
  MEMBER GET ProjectRights<&H5>(OPTIONAL IN Project AS STRING<&H0>) AS
LONG
  MEMBER LET ProjectRights<&H5>(OPTIONAL IN Project AS STRING<&H0>)
  MEMBER CALL RemoveProjectRights<&H6>(IN Project AS STRING<&H0>)
END INTERFACE

INTERFACE IDBIND IAPPItems
  MEMBER GET Count<&H1>() AS LONG
  MEMBER GET Item<&H0>(IN sItem AS VARIANT<&H0>) AS IAPPItem
END INTERFACE

DIM oApp AS IAPPUser
LET oApp = NEW IAPPUser IN "com.server.0"

POWERARRAY Object New!

Purpose The PowerArray object encapsulates the Windows SAFEARRAY structure. Each object contains exactly one SAFEARRAY, and allows you to read, write, and manipulate the elements easily.

The SAFEARRAY is generally considered to be the lowest common denominator of arrays. It's not as fast as a standard PowerBASIC array, but it serves an excellent purpose: It's a "standard" form of array data which can be used to transfer data between programs, modules, and even DLLs created with different versions of the compiler. Other than the possibility of added data types, we do not expect to see the internal format to change in the foreseeable future.

A SAFEARRAY is frequently contained in a VARIANT variable. However, you'll usually find that the array is referenced and identified by a 32-bit pointer to its array descriptor.

Remarks All array operations are executed with METHOD and PROPERTY invocations on a PowerArray object. When you create or examine a PowerArray, the specific data type is identified by the following VT codes. All of them are predefined in the compiler. VT codes numbered above 200 are unique to PowerBASIC. Other programming languages will not recognize them, giving undefined results.

```
%vt_i2         = 2          %vt_ui4         = 19
```

```
%vt_i4          = 3      %vt_i8           = 20
%vt_r4          = 4      %vt_int          = 22
%vt_r8          = 5      %vt_uint         = 23
%vt_cy          = 6      %vt_ptr          = 26
%vt_date        = 7      %vt_userdefined  = 29
%vt_bstr        = 8      %vt_filetime     = 64
%vt_dispatch    = 9      %vt_astr         = 201
%vt_bool        = 11     %vt_stringfix    = 203
%vt_variant     = 12     %vt_wstringfix   = 204
%vt_unknown     = 13     %vt_stringz      = 205
%vt_decimal     = 14     %vt_wstringz     = 206
%vt_i1          = 16     %vt_type         = 211
%vt_ui1         = 17     %vt_ext          = 221
%vt_ui2         = 18     %vt_curx         = 222
```

The array dimensions are stated at the time the array is created by executing the DIM method. The ByRef *Bounds* parameter refers to a PowerBounds UDT which is predefined in the compiler. *Bound* is a PowerBOUND UDT for use with RedimPreserve. It is also predefined in the compiler.

```
TYPE PowerBounds              TYPE PowerBound
  Elements1 AS LONG             Elements AS LONG
  LowBound1 AS LONG             LowBound AS LONG
  Elements2 AS LONG           END TYPE
  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

POWERARRAY Object New!

Purpose The PowerArray object encapsulates the Windows SAFEARRAY structure. Each object contains exactly one SAFEARRAY, and allows you to read, write, and manipulate the elements easily.

The SAFEARRAY is generally considered to be the lowest common denominator of arrays. It's not as fast as a standard PowerBASIC array, but it serves an excellent purpose: It's a "standard" form of array data which can be used to transfer data between programs, modules, and even DLLs created with different versions of the compiler. Other than the possibility of added data types, we do not expect to see the internal format to change in the foreseeable future.

A SAFEARRAY is frequently contained in a VARIANT variable. However, you'll usually find that the array is referenced and identified by a 32-bit pointer to its array descriptor.

Remarks All array operations are executed with METHOD and PROPERTY invocations on a

PowerArray object. When you create or examine a PowerArray, the specific data type is identified by the following VT codes. All of them are predefined in the compiler. VT codes numbered above 200 are unique to PowerBASIC. Other programming languages will not recognize them, giving undefined results.

```
%vt_i2          = 2        %vt_ui4          = 19
%vt_i4          = 3        %vt_i8           = 20
%vt_r4          = 4        %vt_int          = 22
%vt_r8          = 5        %vt_uint         = 23
%vt_cy          = 6        %vt_ptr          = 26
%vt_date        = 7        %vt_userdefined  = 29
%vt_bstr        = 8        %vt_filetime     = 64
%vt_dispatch    = 9        %vt_astr         = 201
%vt_bool        = 11       %vt_stringfix    = 203
%vt_variant     = 12       %vt_wstringfix   = 204
%vt_unknown     = 13       %vt_stringz      = 205
%vt_decimal     = 14       %vt_wstringz     = 206
%vt_i1          = 16       %vt_type         = 211
%vt_ui1         = 17       %vt_ext          = 221
%vt_ui2         = 18       %vt_curx         = 222
```

The array dimensions are stated at the time the array is created by executing the DIM method. The ByRef *Bounds* parameter refers to a PowerBounds UDT which is predefined in the compiler. *Bound* is a PowerBOUND UDT for use with RedimPreserve. It is also predefined in the compiler.

```
TYPE PowerBounds               TYPE PowerBound
  Elements1 AS LONG              Elements AS LONG
  LowBound1 AS LONG              LowBound AS LONG
  Elements2 AS LONG            END TYPE
  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM.   LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

POWERARRAY Object New!

Purpose The PowerArray object encapsulates the Windows SAFEARRAY structure. Each object contains exactly one SAFEARRAY, and allows you to read, write, and manipulate the elements easily.

The SAFEARRAY is generally considered to be the lowest common denominator of arrays. It's not as fast as a standard PowerBASIC array, but it serves an excellent purpose: It's a "standard" form of array data which can be used to transfer data between programs, modules, and even DLLs created with different versions of the compiler. Other than the possibility of added data types, we do not expect to see the internal format to change in the foreseeable future.

A SAFEARRAY is frequently contained in a VARIANT variable. However, you'll usually find that the array is referenced and identified by a 32-bit pointer to its array descriptor.

Remarks

All array operations are executed with METHOD and PROPERTY invocations on a PowerArray object. When you create or examine a PowerArray, the specific data type is identified by the following VT codes. All of them are predefined in the compiler. VT codes numbered above 200 are unique to PowerBASIC. Other programming languages will not recognize them, giving undefined results.

```
%vt_i2          = 2          %vt_ui4          = 19
%vt_i4          = 3          %vt_i8           = 20
%vt_r4          = 4          %vt_int          = 22
%vt_r8          = 5          %vt_uint         = 23
%vt_cy          = 6          %vt_ptr          = 26
%vt_date        = 7          %vt_userdefined  = 29
%vt_bstr        = 8          %vt_filetime     = 64
%vt_dispatch    = 9          %vt_astr         = 201
%vt_bool        = 11         %vt_stringfix    = 203
%vt_variant     = 12         %vt_wstringfix   = 204
%vt_unknown     = 13         %vt_stringz      = 205
%vt_decimal     = 14         %vt_wstringz     = 206
%vt_i1          = 16         %vt_type         = 211
%vt_ui1         = 17         %vt_ext          = 221
%vt_ui2         = 18         %vt_curx         = 222
```

The array dimensions are stated at the time the array is created by executing the [DIM]() method. The ByRef *Bounds* parameter refers to a PowerBounds UDT which is predefined in the compiler. *Bound* is a PowerBOUND UDT for use with [RedimPreserve](). It is also predefined in the compiler.

```
TYPE PowerBounds              TYPE PowerBound
  Elements1 AS LONG             Elements AS LONG
  LowBound1 AS LONG             LowBound AS LONG
  Elements2 AS LONG           END TYPE
  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the [OBJRESULT]() function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a [wide text]() string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a [wide dynamic string]() to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

**METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>**

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

```
TYPE PowerBounds              TYPE PowerBound
  Elements1 AS LONG             Elements AS LONG
  LowBound1 AS LONG             LowBound AS LONG
  Elements2 AS LONG           END TYPE
  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, % vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

POWERARRAY Object New!

Purpose The PowerArray object encapsulates the Windows SAFEARRAY structure. Each object contains exactly one SAFEARRAY, and allows you to read, write, and manipulate the elements easily.

The SAFEARRAY is generally considered to be the lowest common denominator of arrays. It's not as fast as a standard PowerBASIC array, but it serves an excellent purpose: It's a "standard" form of array data which can be used to transfer data between programs, modules, and even DLLs created with different versions of the compiler. Other than the possibility of added data types, we do not expect to see the internal format to change in the foreseeable future.

A SAFEARRAY is frequently contained in a VARIANT variable. However, you'll usually find that the array is referenced and identified by a 32-bit pointer to its array descriptor.

Remarks

All array operations are executed with METHOD and PROPERTY invocations on a PowerArray object. When you create or examine a PowerArray, the specific data type is identified by the following VT codes. All of them are predefined in the compiler. VT codes numbered above 200 are unique to PowerBASIC. Other programming languages will not recognize them, giving undefined results.

```
%vt_i2          = 2       %vt_ui4         = 19
%vt_i4          = 3       %vt_i8          = 20
%vt_r4          = 4       %vt_int         = 22
%vt_r8          = 5       %vt_uint        = 23
%vt_cy          = 6       %vt_ptr         = 26
%vt_date        = 7       %vt_userdefined = 29
%vt_bstr        = 8       %vt_filetime    = 64
%vt_dispatch    = 9       %vt_astr        = 201
%vt_bool        = 11      %vt_stringfix   = 203
%vt_variant     = 12      %vt_wstringfix  = 204
%vt_unknown     = 13      %vt_stringz     = 205
%vt_decimal     = 14      %vt_wstringz    = 206
%vt_i1          = 16      %vt_type        = 211
%vt_ui1         = 17      %vt_ext         = 221
%vt_ui2         = 18      %vt_curx        = 222
```

The array dimensions are stated at the time the array is created by executing the DIM method. The ByRef *Bounds* parameter refers to a PowerBounds UDT which is predefined in the compiler. *Bound* is a PowerBOUND UDT for use with RedimPreserve. It is also predefined in the compiler.

```
TYPE PowerBounds              TYPE PowerBound
  Elements1 AS LONG             Elements AS LONG
  LowBound1 AS LONG             LowBound AS LONG
  Elements2 AS LONG           END TYPE
  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, % vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

POWERARRAY Object New!

Purpose The PowerArray object encapsulates the Windows SAFEARRAY structure. Each object contains exactly one SAFEARRAY, and allows you to read, write, and manipulate the elements easily.

The SAFEARRAY is generally considered to be the lowest common denominator of arrays. It's not as fast as a standard PowerBASIC array, but it serves an excellent purpose: It's a "standard" form of array data which can be used to transfer data between programs, modules, and even DLLs created with different versions of the compiler. Other than the possibility of added data types, we do not expect to see the internal format to change in the foreseeable future.

A SAFEARRAY is frequently contained in a VARIANT variable. However, you'll usually find that the array is referenced and identified by a 32-bit pointer to its array descriptor.

Remarks

All array operations are executed with METHOD and PROPERTY invocations on a PowerArray object. When you create or examine a PowerArray, the specific data type is identified by the following VT codes. All of them are predefined in the compiler. VT codes numbered above 200 are unique to PowerBASIC. Other programming languages will not recognize them, giving undefined results.

```
%vt_i2          = 2        %vt_ui4          = 19
%vt_i4          = 3        %vt_i8           = 20
%vt_r4          = 4        %vt_int          = 22
%vt_r8          = 5        %vt_uint         = 23
%vt_cy          = 6        %vt_ptr          = 26
%vt_date        = 7        %vt_userdefined  = 29
%vt_bstr        = 8        %vt_filetime     = 64
%vt_dispatch    = 9        %vt_astr         = 201
%vt_bool        = 11       %vt_stringfix    = 203
%vt_variant     = 12       %vt_wstringfix   = 204
%vt_unknown     = 13       %vt_stringz      = 205
%vt_decimal     = 14       %vt_wstringz     = 206
%vt_i1          = 16       %vt_type         = 211
%vt_ui1         = 17       %vt_ext          = 221
%vt_ui2         = 18       %vt_curx         = 222
```

The array dimensions are stated at the time the array is created by executing the DIM method. The ByRef *Bounds* parameter refers to a PowerBounds UDT which is predefined in the compiler. *Bound* is a PowerBOUND UDT for use with RedimPreserve. It is also predefined in the compiler.

```
TYPE PowerBounds             TYPE PowerBound
  Elements1 AS LONG            Elements AS LONG
  LowBound1 AS LONG            LowBound AS LONG
  Elements2 AS LONG          END TYPE
  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, % vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

  Elements2 AS LONG             END TYPE
  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

**METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>**

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, % vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

POWERARRAY Object New!

Purpose The PowerArray object encapsulates the Windows SAFEARRAY structure. Each object contains exactly one SAFEARRAY, and allows you to read, write, and manipulate the elements easily.

The SAFEARRAY is generally considered to be the lowest common denominator of arrays. It's not as fast as a standard PowerBASIC array, but it serves an excellent purpose: It's a "standard" form of array data which can be used to transfer data between programs, modules, and even DLLs created with different versions of the compiler. Other than the possibility of added data types, we do not expect to see the internal format to change in the foreseeable future.

A SAFEARRAY is frequently contained in a VARIANT variable. However, you'll usually find that the array is referenced and identified by a 32-bit pointer to its array descriptor.

Remarks

All array operations are executed with METHOD and PROPERTY invocations on a PowerArray object. When you create or examine a PowerArray, the specific data type is identified by the following VT codes. All of them are predefined in the compiler. VT codes numbered above 200 are unique to PowerBASIC. Other programming languages will not recognize them, giving undefined results.

```
%vt_i2          = 2          %vt_ui4         = 19
%vt_i4          = 3          %vt_i8          = 20
%vt_r4          = 4          %vt_int         = 22
%vt_r8          = 5          %vt_uint        = 23
%vt_cy          = 6          %vt_ptr         = 26
%vt_date        = 7          %vt_userdefined = 29
%vt_bstr        = 8          %vt_filetime    = 64
%vt_dispatch    = 9          %vt_astr        = 201
%vt_bool        = 11         %vt_stringfix   = 203
%vt_variant     = 12         %vt_wstringfix  = 204
%vt_unknown     = 13         %vt_stringz     = 205
%vt_decimal     = 14         %vt_wstringz    = 206
%vt_i1          = 16         %vt_type        = 211
%vt_ui1         = 17         %vt_ext         = 221
%vt_ui2         = 18         %vt_curx        = 222
```

The array dimensions are stated at the time the array is created by executing the DIM method. The ByRef *Bounds* parameter refers to a PowerBounds UDT which is predefined in the compiler. *Bound* is a PowerBOUND UDT for use with RedimPreserve. It is also predefined in the compiler.

```
TYPE PowerBounds                 TYPE PowerBound
  Elements1 AS LONG                Elements AS LONG
  LowBound1 AS LONG                LowBound AS LONG
  Elements2 AS LONG              END TYPE
  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, % vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

```
METHOD ELEMENTPTR (ByVal Index1&, Opt ByVal Index2&, _
                   Opt ByVal Index3&, Opt ByVal Index4&)
AS LONG <11>
```

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. ```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

POWERARRAY Object New!

Purpose The PowerArray object encapsulates the Windows SAFEARRAY structure. Each object contains exactly one SAFEARRAY, and allows you to read, write, and manipulate the elements easily.

The SAFEARRAY is generally considered to be the lowest common denominator of arrays. It's not as fast as a standard PowerBASIC array, but it serves an excellent purpose: It's a "standard" form of array data which can be used to transfer data between programs, modules, and even DLLs created with different versions of the compiler. Other than the possibility of added data types, we do not expect to see the internal format to change in the foreseeable future.

A SAFEARRAY is frequently contained in a VARIANT variable. However, you'll usually find that the array is referenced and identified by a 32-bit pointer to its array descriptor.

Remarks

All array operations are executed with METHOD and PROPERTY invocations on a PowerArray object. When you create or examine a PowerArray, the specific data type is identified by the following VT codes. All of them are predefined in the compiler. VT codes numbered above 200 are unique to PowerBASIC. Other programming languages will not recognize them, giving undefined results.

```
%vt_i2          = 2         %vt_ui4          = 19
%vt_i4          = 3         %vt_i8           = 20
%vt_r4          = 4         %vt_int          = 22
%vt_r8          = 5         %vt_uint         = 23
%vt_cy          = 6         %vt_ptr          = 26
%vt_date        = 7         %vt_userdefined  = 29
%vt_bstr        = 8         %vt_filetime     = 64
%vt_dispatch    = 9         %vt_astr         = 201
%vt_bool        = 11        %vt_stringfix    = 203
%vt_variant     = 12        %vt_wstringfix   = 204
%vt_unknown     = 13        %vt_stringz      = 205
%vt_decimal     = 14        %vt_wstringz     = 206
%vt_i1          = 16        %vt_type         = 211
%vt_ui1         = 17        %vt_ext          = 221
%vt_ui2         = 18        %vt_curx         = 222
```

The array dimensions are stated at the time the array is created by executing the DIM method. The ByRef *Bounds* parameter refers to a PowerBounds UDT which is predefined in the compiler. *Bound* is a PowerBOUND UDT for use with RedimPreserve. It is also predefined in the compiler.

```
TYPE PowerBounds
  Elements1 AS LONG
  LowBound1 AS LONG
  Elements2 AS LONG
  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

```
TYPE PowerBound
  Elements AS LONG
  LowBound AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

**METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>**

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

Purpose The PowerArray object encapsulates the Windows SAFEARRAY structure. Each object contains exactly one SAFEARRAY, and allows you to read, write, and manipulate the elements easily.

The SAFEARRAY is generally considered to be the lowest common denominator of arrays. It's not as fast as a standard PowerBASIC array, but it serves an excellent purpose: It's a "standard" form of array data which can be used to transfer data between programs, modules, and even DLLs created with different versions of the compiler. Other than the possibility of added data types, we do not expect to see the internal format to change in the foreseeable future.

A SAFEARRAY is frequently contained in a VARIANT variable. However, you'll usually find that the array is referenced and identified by a 32-bit pointer to its array descriptor.

Remarks

All array operations are executed with METHOD and PROPERTY invocations on a PowerArray object. When you create or examine a PowerArray, the specific data type is identified by the following VT codes. All of them are predefined in the compiler. VT codes numbered above 200 are unique to PowerBASIC. Other programming languages will not recognize them, giving undefined results.

```
%vt_i2          = 2      %vt_ui4          = 19
%vt_i4          = 3      %vt_i8           = 20
%vt_r4          = 4      %vt_int          = 22
%vt_r8          = 5      %vt_uint         = 23
%vt_cy          = 6      %vt_ptr          = 26
%vt_date        = 7      %vt_userdefined  = 29
%vt_bstr        = 8      %vt_filetime     = 64
%vt_dispatch    = 9      %vt_astr         = 201
%vt_bool        = 11     %vt_stringfix    = 203
%vt_variant     = 12     %vt_wstringfix   = 204
%vt_unknown     = 13     %vt_stringz      = 205
%vt_decimal     = 14     %vt_wstringz     = 206
%vt_i1          = 16     %vt_type         = 211
%vt_ui1         = 17     %vt_ext          = 221
%vt_ui2         = 18     %vt_curx         = 222
```

The array dimensions are stated at the time the array is created by executing the DIM method. The ByRef *Bounds* parameter refers to a PowerBounds UDT which is predefined in the compiler. *Bound* is a PowerBOUND UDT for use with RedimPreserve. It is also predefined in the compiler.

```
TYPE PowerBounds              TYPE PowerBound
  Elements1 AS LONG             Elements AS LONG
  LowBound1 AS LONG             LowBound AS LONG
  Elements2 AS LONG           END TYPE
  LowBound2 AS LONG
  Elements3 AS LONG
  LowBound3 AS LONG
  Elements4 AS LONG
  LowBound4 AS LONG
END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

```
METHOD ELEMENTPTR (ByVal Index1&, Opt ByVal Index2&, _
                   Opt ByVal Index3&, Opt ByVal Index4&)
AS LONG <11>
```

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, % vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

END TYPE
```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, % vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

```

This class is named PowerArray, and the interface is named IPowerArray. If any of the following operations should fail, the OBJRESULT function will return a non-zero result rather than %S_OK (zero).

IPowerArray Methods/Properties

METHOD ARRAYBASE () AS DWORD <1>

This method returns the address of the first element of the array.

METHOD ARRAYDESC () AS DWORD <2>

This method returns the address of the SAFEARRAY descriptor.

PROPERTY GET ARRAYINFO () AS WString <3>

You can attach a wide text string to an array for informational or documentation. This Get Property retrieves the info string, if one is present.

PROPERTY SET ARRAYINFO () = *WString* <3>

You can attach a wide text string to an array for informational or documentation. This Set Property assigns a wide dynamic string to the array.

METHOD CLONE (PowerArray) <4>

The parameter PowerArray is another object of the same class as this object, which is PowerArray. An exact duplicate of the SafeArray in the parameter is created, and stored in this object.

METHOD COPYFROMVARIANT (ByRef *Variant*) <5>

An exact copy is made of the SafeArray contained in the parameter *Variant*. The array copy is stored in this PowerArray object.

METHOD COPYTOVARIANT (ByRef *Variant*) <6>

An exact copy is made of the SafeArray in this object. The array copy is stored in the parameter *Variant*. Only arrays of data items which are Automation compatible may be stored in a Variant. Data types which are PowerBASIC-Specific cannot be copied.

METHOD DIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <9>

Dimensions (creates) a new array. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, %vt_wstringz, and %vt_type.

METHOD ERASE () <10>

The contained array is destroyed and the object is then considered empty.

METHOD ELEMENTPTR (ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*)
AS LONG <11>

Calculates and retrieves the address of the data element specified by the *Index* parameter(s).

METHOD ELEMENTSIZE () <12>

Retrieves the storage size (in bytes) of each data element of the array.

METHOD LBOUND (*Subscript&*) AS LONG <13>

Retrieves the lower bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD LOCK () <14>

Increments the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

METHOD MOVEFROMVARIANT (ByRef *Variant*) <17>

Transfers ownership of the SafeArray contained in the *variant* parameter to this PowerArray object. The variant is then changed to %vt_empty.

METHOD MOVETOVARIANT (ByRef *Variant*) <18>

Transfers ownership of the SafeArray contained in this PowerArray object to the *variant* parameter. The PowerArray object is then changed to empty.

METHOD REDIM (ByVal *VT&*, ByVal *Subscripts&*, ByRef *Bounds*, OPTIONAL ByVal *SIZE*) <19>

REDIM allows the SafeArray to be erased and re-dimensioned to a new size. It is really just a shortcut for the two-step process of ERASE, followed by DIM. The *VT&* parameter is specified by one of the %VT values listed in remarks. *Subscripts&* is the number of dimensions (1 to 4), *Bounds* is a PowerBounds UDT which is prefilled with the lower bound and size of each dimension. The optional parameter *SIZE* tells the size (in bytes) of each element. *SIZE* is only used with %vt_stringfix, %vt_wstringfix, %vt_stringz, % vt_wstringz, and %vt_type.

METHOD REDIMPRESERVE (ByRef *Bound*) <20>

REDIMPRESERVE allows the least significant (rightmost) bound to be changed to a new size. The remaining data items in the array are preserved. *Bound* is a PowerBound UDT which is prefilled with the lower bound and size of the dimension to be changed.

METHOD RESET () <21>

All elements in the SafeArray are set back to their initial, default value. Numerics are set to zero, strings to zero-length, variants to %vt_empty, and object variables are set to nothing. The array memory is not deallocated.

METHOD SUBSCRIPTS () <22>

Retrieves the number of dimensions (subscripts) for this array.

METHOD UBOUND (*Subscript&*) AS LONG <23>

Retrieves the upper bound number for the dimension specified by the *Subscript&* parameter. The first subscript is 1, the second is 2, etc.

METHOD UNLOCK () <24>

Decrements the lock count of the SAFEARRAY. Locks can be nested, but there must be an equal number of Unlocks executed.

**METHOD VALUEGET (ByRef *GetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <25>**

Calculates and retrieves the value of the array element specified by the *Index* parameter(s). This value is then assigned to the *GetVar* variable. It is the programmer's responsibility to ensure that the type of *GetVar* matches the type of the array precisely.

**METHOD VALUESET (ByRef *SetVar*, ByVal *Index1&*, Opt ByVal *Index2&*, _
Opt ByVal *Index3&*, Opt ByVal *Index4&*) AS LONG <26>**

Assigns the value of the *SetVar* variable to the array element specified by the *Index* parameter(s). It is the programmer's responsibility to ensure that the type of *SetVar* matches the type of the array precisely.

METHOD VALUETYPE () <27>

Retrieves the %VT code which describes the data contained in this array. The %VT codes are listed in the Remark section above.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax *The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).*

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

`REMOVE <11> (`*`Index`*` AS Long)`

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`REPLACE <12> (Index AS Long, PowerItem AS Variant)`

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

`CLEAR <1>`

All *PowerItems* are removed from the StackCollection.

`COUNT <2> AS Long`

The number of data items currently contained in the StackCollection is returned to the caller.

`POP <3> AS Variant`

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`PUSH <4> (PowerItem AS Variant)`

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection

A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax

The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

`CLEAR <1>`

All *PowerItems* are removed from the QueueCollection.

`COUNT <2> AS Long`

The number of data items currently contained in the QueueCollection is returned to the

caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose

A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the

same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

```
IndexVar& = ObjectVar.INDEX(0)
```

The above example retrieves the current index number, without changing it, and assigns it

to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL

interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose

A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as

either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved

sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If

the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax *The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

Example

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may

be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

[LET] *VrntVar* = *TypeVar* AS STRING

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

***CollObj*.Add(*Key$$*, *UDTVar* AS STRING)**

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

IndexVar& = ObjectVar.INDEX(0)

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position

number, or sequentially in ascending or descending sequence.

Syntax *The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).*

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is

successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection

A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax

The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should

be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

```
IndexVar& = ObjectVar.INDEX(0)
```

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax *The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the

caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
```

<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

Example

COLLECTION Object Group New!

Purpose

A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`REPLACE <13> (PowerKey AS WString, PowerItem AS Variant)`

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`SORT <14> (Flags AS Long)`

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax *The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

`ADD <3> (PowerItem AS Variant)`

The *PowerItem* variant is added to the end of the LinkListCollection.

`CLEAR <4>`

All *PowerItems* are removed from the LinkListCollection.

`COUNT <5> AS Long`

The number of data items currently contained in the LinkListCollection is returned to the caller.

`FIRST <1> AS Long`

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

`INDEX <6> (Index AS Long) AS Long`

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

`IndexVar& = ObjectVar.INDEX(0)`

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

`INSERT <7> (Index AS Long, PowerItem AS Variant)`

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

`ITEM <8> (Index AS Long) AS Variant`

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection

A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

[LET] *VrntVar* = *TypeVar* AS STRING

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

***CollObj*.Add(*Key$$*, *UDTVar* AS STRING)**

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`FIRST <1> AS Long`

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

`INDEX <8> (`*`Index`*` AS Long) AS Long`

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

IndexVar& **=** ***ObjectVar*****.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

`ITEM <9> (`*`PowerKey`*` AS WString) AS Variant`

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`LAST <10> AS Long`

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

`NEXT <2> AS Variant`

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

`PREVIOUS <11> AS Variant`

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

`REMOVE <12> (`*`PowerKey`*` AS WString)`

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`REPLACE <13> (`*`PowerKey`*` AS WString, `*`PowerItem`*` AS Variant)`

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`SORT <14> (`*`Flags`*` AS Long)`

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

<*ObjectVar*>.membername(*params*)

***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax *The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose

A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

```
IndexVar& = ObjectVar.INDEX(0)
```

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax *The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax *The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

IndexVar& = _ObjectVar_.INDEX(0)

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection

A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax

The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax *The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose

A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL

interface).

***<ObjectVar>*.membername(*params*)**
***RetVal* = *<ObjectVar>*.membername(*params*)**
<ObjectVar>*.membername(*params*) TO *ReturnVariable

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

`POP <3> AS Variant`

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`PUSH <4> (PowerItem AS Variant)`

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

`CLEAR <1>`

All *PowerItems* are removed from the QueueCollection.

`COUNT <2> AS Long`

The number of data items currently contained in the QueueCollection is returned to the caller.

`DEQUEUE <3> AS Variant`

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`ENQUEUE <4> (PowerItem AS Variant)`

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

`PREVIOUS <10> AS Variant`

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

`REMOVE <11> (Index AS Long)`

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`REPLACE <12> (Index AS Long, PowerItem AS Variant)`

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

`CLEAR <1>`

All *PowerItems* are removed from the StackCollection.

`COUNT <2> AS Long`

The number of data items currently contained in the StackCollection is returned to the caller.

`POP <3> AS Variant`

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`PUSH <4> (PowerItem AS Variant)`

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection

A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax

The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

Example

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection

A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax

The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose

A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

***<ObjectVar>*.membername(*params*)**
***RetVal* = *<ObjectVar>*.membername(*params*)**
<ObjectVar>*.membername(*params*) TO *ReturnVariable

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

THREAD Object New!

Purpose A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal* AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER

 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
```

```
  ...
  MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL  =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL  =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL  =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL  =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions

Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

THREAD Object New!

Purpose

A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

`METHOD CLOSE() <2>`

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

`METHOD EQUALS(ObjectVar AS InterfaceName) AS Long <3>`

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

`METHOD HANDLE() AS Long <4>`

Retrieves the handle of the thread for use with Windows API functions.

`METHOD ID() AS Long <5>`

Retrieves the ID of the thread for use with Windows API functions.

`METHOD ISALIVE() AS Long <6>`

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

`METHOD JOIN(ThreadObjectVar AS InterfaceName, TimeOutVal AS Long) <7>`

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER

 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL  =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL  =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL  =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL  =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions

Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

THREAD Object New!

Purpose

A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal* AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER

 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
```

```
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

See also PowerTime, THREAD Code Group

Example

```
CLASS MyClass
  INSTANCE ThreadParam as DataFace

  THREAD METHOD MAIN() AS LONG
    x& = ThreadParam.GetANumber()
    MsgBox DEC$(x&)
  END METHOD

  INTERFACE MyFace
    INHERIT IPOWERTHREAD

    METHOD abc
      END METHOD
    END INTERFACE
END CLASS

CLASS DataClass
  INTERFACE DataFace
    INHERIT DUAL

    METHOD GetANumber() AS LONG
    METHOD = 77
  END METHOD

  END INTERFACE
END CLASS

FUNCTION PBMain()
  LOCAL xx AS MyFace
  LET xx = CLASS "MyClass"

  LOCAL oo AS DataFace
  LET oo = CLASS "DataClass"
```

```
  xx.launch(oo)
  xx.join(xx, 0)
END FUNCTION
```

THREAD Object New!

Purpose

A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal* AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER

 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

See also PowerTime, THREAD Code Group

Example

```
CLASS MyClass
  INSTANCE ThreadParam as DataFace
```

```
  THREAD METHOD MAIN() AS LONG
    x& = ThreadParam.GetANumber()
    MsgBox DEC$(x&)
  END METHOD

  INTERFACE MyFace
    INHERIT IPOWERTHREAD

    METHOD abc
      END METHOD
    END INTERFACE
END CLASS

CLASS DataClass
  INTERFACE DataFace
    INHERIT DUAL

    METHOD GetANumber() AS LONG
    METHOD = 77
  END METHOD

  END INTERFACE
END CLASS

FUNCTION PBMain()
  LOCAL xx AS MyFace
  LET xx = CLASS "MyClass"

  LOCAL oo AS DataFace
  LET oo = CLASS "DataClass"

  xx.launch(oo)
  xx.join(xx, 0)
END FUNCTION

4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

`METHOD CLOSE() <2>`

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

`METHOD HANDLE() AS Long <4>`

Retrieves the handle of the thread for use with Windows API functions.

`METHOD ID() AS Long <5>`

Retrieves the ID of the thread for use with Windows API functions.

`METHOD ISALIVE() AS Long <6>`

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal* AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER
```

```
 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE         = -15
%THREAD_PRIORITY_LOWEST       =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL       =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST      =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE         = -15
%THREAD_PRIORITY_LOWEST       =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL       =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST      =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all

the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

See also PowerTime, THREAD Code Group

Example

```
CLASS MyClass
  INSTANCE ThreadParam as DataFace

  THREAD METHOD MAIN() AS LONG
    x& = ThreadParam.GetANumber()
    MsgBox DEC$(x&)
  END METHOD

  INTERFACE MyFace
    INHERIT IPOWERTHREAD

    METHOD abc
      END METHOD
    END INTERFACE
END CLASS

CLASS DataClass
  INTERFACE DataFace
    INHERIT DUAL

    METHOD GetANumber() AS LONG
    METHOD = 77
  END METHOD

  END INTERFACE
END CLASS

FUNCTION PBMain()
  LOCAL xx AS MyFace
  LET xx = CLASS "MyClass"
```

```
  LOCAL oo AS DataFace
  LET oo = CLASS "DataClass"

  xx.launch(oo)
  xx.join(xx, 0)
END FUNCTION
```

THREAD Object New!

Purpose

A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

***<ObjectVar>.membername*(*params*)**
***RetVal* = *<ObjectVar>.membername*(*params*)**
<ObjectVar>.membername*(*params*) TO *ReturnVariable

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal*

AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a
option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER

 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL  =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL  =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL  =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL  =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved

and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

See also PowerTime, THREAD Code Group

Example

```
CLASS MyClass
  INSTANCE ThreadParam as DataFace

  THREAD METHOD MAIN() AS LONG
    x& = ThreadParam.GetANumber()
    MsgBox DEC$(x&)
  END METHOD

  INTERFACE MyFace
    INHERIT IPOWERTHREAD

    METHOD abc
      END METHOD
    END INTERFACE
END CLASS

CLASS DataClass
  INTERFACE DataFace
    INHERIT DUAL

    METHOD GetANumber() AS LONG
    METHOD = 77
  END METHOD

  END INTERFACE
END CLASS

FUNCTION PBMain()
  LOCAL xx AS MyFace
  LET xx = CLASS "MyClass"

  LOCAL oo AS DataFace
  LET oo = CLASS "DataClass"

  xx.launch(oo)
  xx.join(xx, 0)
END FUNCTION
```

THREAD Object New!

Purpose

A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal* AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER
```

```
 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL  =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL  =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL  =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL  =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all

the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

THREAD Object New!

Purpose

A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params)* TO *ReturnVariable

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal*

AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER

 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved

and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

`METHOD RESUME() AS Long <11>`

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

`PROPERTY GET STACKSIZE() AS Long <13>`

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

`PROPERTY SET STACKSIZE(Long) <13>`

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

`METHOD SUSPEND() AS Long <14>`

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

`METHOD TIMECREATE() AS Quad <16>`

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

`METHOD TIMEEXIT() AS Quad <17>`

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

`METHOD TIMEKERNEL() AS Quad <18>`

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

`METHOD TIMEUSER() AS Quad <19>`

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

THREAD Object New!

Purpose A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal* AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER
```

```
 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all

the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

`METHOD TIMECREATE() AS Quad <16>`

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

`METHOD TIMEEXIT() AS Quad <17>`

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

`METHOD TIMEKERNEL() AS Quad <18>`

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

`METHOD TIMEUSER() AS Quad <19>`

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions

Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal*

AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER

 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved

and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

THREAD Object New!

Purpose A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal* AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER
```

```
 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all

the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

Example

```
CLASS MyClass
  INSTANCE ThreadParam as DataFace

  THREAD METHOD MAIN() AS LONG
    x& = ThreadParam.GetANumber()
    MsgBox DEC$(x&)
  END METHOD

  INTERFACE MyFace
    INHERIT IPOWERTHREAD

    METHOD abc
      END METHOD
    END INTERFACE
END CLASS

CLASS DataClass
  INTERFACE DataFace
    INHERIT DUAL

    METHOD GetANumber() AS LONG
    METHOD = 77
  END METHOD

  END INTERFACE
END CLASS

FUNCTION PBMain()
  LOCAL xx AS MyFace
  LET xx = CLASS "MyClass"
```

```
  LOCAL oo AS DataFace
  LET oo = CLASS "DataClass"

  xx.launch(oo)
  xx.join(xx, 0)
END FUNCTION
```

THREAD Object New!

Purpose

A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal*

AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, [Long Integer], or [Dword]. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER

 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved

and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

`METHOD RESUME() AS Long <11>`

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

`PROPERTY GET STACKSIZE() AS Long <13>`

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

`PROPERTY SET STACKSIZE(Long) <13>`

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

`METHOD SUSPEND() AS Long <14>`

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

`METHOD TIMECREATE() AS Quad <16>`

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

`METHOD TIMEEXIT() AS Quad <17>`

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

`METHOD TIMEKERNEL() AS Quad <18>`

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

`METHOD TIMEUSER() AS Quad <19>`

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal* AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER
```

```
 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE         = -15
%THREAD_PRIORITY_LOWEST       =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL       =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST      =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE         = -15
%THREAD_PRIORITY_LOWEST       =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL       =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST      =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all

the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

See also PowerTime, THREAD Code Group

Example

```
CLASS MyClass
  INSTANCE ThreadParam as DataFace

  THREAD METHOD MAIN() AS LONG

THREAD Object New!

Purpose

A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal*

AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER

 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved

and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal* AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER
```

```
 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE          = -15
%THREAD_PRIORITY_LOWEST        =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL        =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST       =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all

the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions

Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal*

AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER

 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE         = -15
%THREAD_PRIORITY_LOWEST       =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL       =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST      =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE         = -15
%THREAD_PRIORITY_LOWEST       =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL       =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST      =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved

and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

`METHOD RESUME() AS Long <11>`

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

`PROPERTY GET STACKSIZE() AS Long <13>`

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

`PROPERTY SET STACKSIZE(Long) <13>`

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

`METHOD SUSPEND() AS Long <14>`

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

`METHOD TIMECREATE() AS Quad <16>`

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

`METHOD TIMEEXIT() AS Quad <17>`

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

`METHOD TIMEKERNEL() AS Quad <18>`

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

`METHOD TIMEUSER() AS Quad <19>`

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

Example

```
CLASS MyClass
  INSTANCE ThreadParam as DataFace

  THREAD METHOD MAIN() AS LONG
    x& = ThreadParam.GetANumber()
    MsgBox DEC$(x&)
  END METHOD

  INTERFACE MyFace
    INHERIT IPOWERTHREAD

    METHOD abc
      END METHOD
    END INTERFACE
END CLASS

CLASS DataClass
  INTERFACE DataFace
    INHERIT DUAL

    METHOD GetANumber() AS LONG
    METHOD = 77
  END METHOD

  END INTERFACE
END CLASS

FUNCTION PBMain()
  LOCAL xx AS MyFace
  LET xx = CLASS "MyClass"

  LOCAL oo AS DataFace
  LET oo = CLASS "DataClass"

  xx.launch(oo)
  xx.join(xx, 0)
END FUNCTION

THREAD Object New!

Purpose

A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal* AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, Long Integer, or Dword. In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER
```

```
 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE         = -15
%THREAD_PRIORITY_LOWEST       =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL       =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST      =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE         = -15
%THREAD_PRIORITY_LOWEST       =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL       =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST      =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

METHOD RESUME() AS Long <11>

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

PROPERTY GET STACKSIZE() AS Long <13>

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

PROPERTY SET STACKSIZE(Long) <13>

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

METHOD SUSPEND() AS Long <14>

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all

the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

METHOD TIMECREATE() AS Quad <16>

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

METHOD TIMEEXIT() AS Quad <17>

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

METHOD TIMEKERNEL() AS Quad <18>

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

METHOD TIMEUSER() AS Quad <19>

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions

Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

THREAD Object New!

Purpose

A

is a "program-within-a-program", that runs concurrently with the main thread and other threads in a single application program. Threads provide powerful ways for an application to perform several tasks at the same time. When executed on a computer with a multi-core CPU, threads can improve performance to a remarkable level.

THREAD objects offer a collection of methods which allow you to easily create and maintain additional threads of execution in your programs.

A thread can be completely encapsulated (contained) within a thread object. Encapsulation makes an object the perfect vehicle to host a thread. With thread objects, you'll have easy access to multiple thread parameters, private methods, and thread local storage of data. In short, a complete program-within-a-program which can be executed with ease.

We liken this to the concept that "Threads are Alive". When a thread object is created and launched, it takes on a life of its own. It lives (and executes) until its lifetime is over and the thread ends. The life of the thread parallels the life of the object which makes it quite easy to manage.

PowerBASIC provides a pre-defined interface named "IPowerThread", which is a DUAL interface (Dispatch and direct access). When you create a thread object, you first inherit IPowerThread, giving you immediate access to all of its member methods. Next, you add a THREAD METHOD, a special form of private CLASS METHOD, which is automatically executed when the thread is launched.

It's important to remember that the THREAD METHOD you create contains the code which will be executed in the thread. When you start the thread (by calling the LAUNCH method), it executes your THREAD METHOD. When you reach the end of the THREAD METHOD, the thread ends, and its lifetime is over. The THREAD METHOD acts just like the MAIN (or PBMAIN) function in your executable.

You may give the THREAD METHOD any name you wish. However, it is recommended you name it MAIN or PBMAIN. This bit of self-documentation will be a simple reminder of the functionality when you review the code a year from now! Generally speaking, most thread objects consist primarily of CLASS METHODS which are called from the THREAD METHOD. If there are any Member Methods (visible from outside the class), they are not usually called from within the thread. Instead, they are typically called from other threads to monitor the status and progress.

There must be exactly one THREAD METHOD per Class. No more. No less. The THREAD METHOD is executed automatically; it may never be called from within your program.

Instance variables are declared just as in any other class. Unique parameters are passed to each object when it is launched. Finally, public methods and properties may be added to monitor and manipulate the life of your thread.

Here's a synopsis of THREAD OBJECT usage:

1. Create a class with an interface which inherits IPowerThread.
2. Create a THREAD METHOD, best named MAIN or PBMAIN.
3. Create an INSTANCE variable named THREADPARAM which will hold the parameter(s) you choose to pass to the thread when it begins execution. This is usually another object variable.
4. Create CLASS METHODS as needed, which will be called from the THREAD METHOD for support of that code.
5. From the main thread, create an object variable of the thread class and interface.
6. Call the LAUNCH method, passing the appropriate parameter to be used as THREADPARAM. Your thread is now running and alive.

Syntax

<*ObjectVar*>.*membername*(*params*)
***RetVal* = <*ObjectVar*>.*membername*(*params*)**
<*ObjectVar*>.*membername*(*params*) TO *ReturnVariable*

Remarks

With the advent of multi-core CPU's and multi-CPU computers, it's clearly desirable to encapsulate all of the information about a particular thread in a single component. We recommend that all new code use THREAD OBJECTS exclusively, rather than the Thread Code Group. Thread objects provide much greater control, and much better thread parameter handling for the programmer.

IPowerThread Methods

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

METHOD CLOSE() <2>

Releases the thread handle of this thread. Note that it does not stop a thread if it is still running; it simply releases the thread handle (i.e., the resources used to track the thread).

Thread handles should not be released until there is no further need to use other thread methods or properties. If a thread does not need to be monitored, its handle can be released immediately. The thread resources will be freed automatically when the thread terminates naturally.

THREADCOUNT continues to report a thread tally that will include threads whose handle has already been released. A thread ID value may not be used interchangeably with a thread handle value.

METHOD EQUALS(*ObjectVar* AS *InterfaceName*) AS *Long* <3>

Compares the parameter *ObjectVar* to determine if it references the same object as this object. If they both reference the same object, true (-1) is returned; if not, false (0) is returned.

METHOD HANDLE() AS Long <4>

Retrieves the handle of the thread for use with Windows API functions.

METHOD ID() AS Long <5>

Retrieves the ID of the thread for use with Windows API functions.

METHOD ISALIVE() AS Long <6>

Checks the thread to see if it is currently "alive". If the thread has been launched, but has not yet ended, the value true (-1) is returned; if not, the value false (0) is returned.

METHOD JOIN(*ThreadObjectVar* AS *InterfaceName*, *TimeOutVal*

AS Long) <7>

Waits for the thread referenced by *ThreadObjectVar* to complete before execution of this thread continues. *TimeOutVal* specifies the maximum length of time to wait, in MilliSeconds. If *TimeOutVal* is zero (0), the time to wait is infinite.

METHOD LAUNCH(ByRef *Param* as *UDT*) <8>

LAUNCH begins execution of the thread, passing parameter data to it. Since the thread is hosted by an object, it is only fitting that the parameter data be contained in the most robust form, another object.

THREADPARAM is a mandatory Instance variable which you must define in each thread class. It is normally declared as the interface name of your choice:

```
INSTANCE ThreadParam as MyInterface
```

When the thread begins, PowerBASIC automatically creates a copy of the LAUNCH parameter, and assigns it to ThreadParam. Since it is stored in an Instance variable, it is visible to all of your code in your member methods, yet is kept private from the rest of the program. The use of an object as the parameter is the normally the best choice, as it allows virtually any number of data items to be contained.

In simpler cases, you may choose to declare THREADPARAM as a

, [Long Integer](), or [Dword](). In that case, you must pass the launch parameter using a option, to override the expected object variable.

```
INSTANCE ThreadParam as LONG
...
MyThread.Launch(ByVal MyNumber&)
```

Of course, the Pointer parameter option can be used to pass a pointer to any variable, of any type. For example, it could be used to pass a used-defined type if that fits your needs:

```
INSTANCE ThreadParam AS MyType POINTER

 THREAD METHOD MyMethod() AS LONG
   xyz# = ThreadParam.member1
   ... other code
END METHOD
...
MyThread.Launch(ByVal VARPTR(MyType))
```

PROPERTY GET PRIORITY() AS Long <9>

Retrieves the priority value for this thread. The thread priority value is one of the following:

```
%THREAD_PRIORITY_IDLE         = -15
%THREAD_PRIORITY_LOWEST       =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL       =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST      =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

PROPERTY SET PRIORITY (LEVEL AS Long) <9>

Sets the Priority Value for this thread. The thread priority value must be one of the following:

```
%THREAD_PRIORITY_IDLE         = -15
%THREAD_PRIORITY_LOWEST       =  -2
%THREAD_PRIORITY_BELOW_NORMAL =  -1
%THREAD_PRIORITY_NORMAL       =   0
%THREAD_PRIORITY_ABOVE_NORMAL =  +1
%THREAD_PRIORITY_HIGHEST      =  +2
%THREAD_PRIORITY_TIME_CRITICAL= +15
```

METHOD RESULT() AS Long <10>

If the thread has ended, the result value returned by the THREAD METHOD is retrieved

and returned to the caller. The result may be any integral value in the range of a long integer. However, you should avoid using the number &H103 (decimal 259), as that is the value used by Windows to signify that the thread is still running.

If the result is retrieved successfully, the OBJRESULT is set to %S_OK (0). If the thread has not ended, the value zero (0) is returned, and the OBJRESULT is set to %S_FALSE (1).

`METHOD RESUME() AS Long <11>`

Resumes execution of a suspended thread. The suspend count of the thread is decremented. When it reaches zero (0), execution of the thread resumes. If the resume is successful, the prior suspend count is returned; otherwise, -1 is returned.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running at that time.

`PROPERTY GET STACKSIZE() AS Long <13>`

Retrieves the size of the stack for this thread. If the value returned is zero (0), the thread StackSize is the same as that of the main thread.

`PROPERTY SET STACKSIZE(Long) <13>`

Sets the size of the stack for this thread to the value specified by the parameter. The value should always be specified in multiples of 64K (65536). PROPERTY SET must only be executed prior to thread execution with LAUNCH, or it will be ignored. If no PROPERTY SET STACKSIZE is executed, the size of the stack for the main thread will be used for this thread.

`METHOD SUSPEND() AS Long <14>`

Suspends execution of the thread. The suspend count of the thread is incremented. If the suspend was successful, the suspend count is returned; otherwise, -1 is returned.

If SUSPEND is executed prior to LAUNCH of the thread, the suspend count is incremented, and the subsequent LAUNCH is treated as a suspended launch. That is, all the necessary setup tasks are performed, but the thread is suspended just before execution of your THREAD METHOD begins. You can continue execution with RESUME.

A thread can suspend itself with SUSPEND (which increments the suspend count), but logically, cannot RESUME itself because it is not running while suspended.

`METHOD TIMECREATE() AS Quad <16>`

Retrieves the date and time-of-day of the thread creation, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time.

`METHOD TIMEEXIT() AS Quad <17>`

Retrieves the date and time-of-day of the thread exit, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format of Month/Day/Year/Time. If the thread has not yet exited, the return value is undefined.

`METHOD TIMEKERNEL() AS Quad <18>`

Retrieves the amount of time this thread has spent in kernel mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

`METHOD TIMEUSER() AS Quad <19>`

Retrieves the amount of time this thread has spent in user mode, and returns it as a Quad Integer value. The internal format of the value is that of a FILETIME structure, so you can use the PowerTime object to convert it to a human readable format.

Restrictions Functions from the Thread Code Group and THREAD OBJECTS may co-exist in the same application. However, it is important that they not be intermixed when you reference one particular thread.

See also PowerTime, THREAD Code Group

Example

```
CLASS MyClass
  INSTANCE ThreadParam as DataFace

  THREAD METHOD MAIN() AS LONG
    x& = ThreadParam.GetANumber()
    MsgBox DEC$(x&)
  END METHOD

  INTERFACE MyFace
    INHERIT IPOWERTHREAD

    METHOD abc
      END METHOD
    END INTERFACE
END CLASS

CLASS DataClass
  INTERFACE DataFace
    INHERIT DUAL

PowerTime Object New!

Purpose A PowerTime Object contains a date and time value, allowing easy calculations. The internal representation emulates the Windows FILETIME structure as a quad-integer. This value represents the number of 100-nanosecond intervals since January 1, 1601. A nanosecond is one-billionth of a second.

You create a PowerTime object the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL MyTime AS IPowerTime
LET MyTime = CLASS "PowerTime"
```

Once you have created a PowerTime object, you can manipulate it using the member methods. The IPowerTime interface is DUAL -- member methods may be referenced using either Direct or Dispatch form.

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

PowerTime Object New!

Purpose

A PowerTime Object contains a date and time value, allowing easy calculations. The internal representation emulates the Windows FILETIME structure as a quad-integer. This value represents the number of 100-nanosecond intervals since January 1, 1601. A nanosecond is one-billionth of a second.

You create a PowerTime object the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL MyTime AS IPowerTime
LET MyTime = CLASS "PowerTime"
```

Once you have created a PowerTime object, you can manipulate it using the member methods. The IPowerTime interface is DUAL -- member methods may be referenced using either Direct or Dispatch form.

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the

PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

Example

PowerTime Object New!

Purpose A PowerTime Object contains a date and time value, allowing easy calculations. The internal representation emulates the Windows FILETIME structure as a quad-integer. This value represents the number of 100-nanosecond intervals since January 1, 1601. A nanosecond is one-billionth of a second.

You create a PowerTime object the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL MyTime AS IPowerTime
LET MyTime = CLASS "PowerTime"
```

Once you have created a PowerTime object, you can manipulate it using the member methods. The IPowerTime interface is DUAL -- member methods may be referenced using either Direct or Dispatch form.

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal

***Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)**

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

`Today <38> ()`

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

`ToLocalTime <39> ()`

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

`ToUTC <40> ()`

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

`Year <42> () as Long`

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

`AddDays <1> (ByVal Days&)`

Adds the specified number of days to the value of this object. You can subtract days by

using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

Example

PowerTime Object New!

Purpose

A PowerTime Object contains a date and time value, allowing easy calculations. The internal representation emulates the Windows FILETIME structure as a quad-integer. This value represents the number of 100-nanosecond intervals since January 1, 1601. A nanosecond is one-billionth of a second.

You create a PowerTime object the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL MyTime AS IPowerTime
LET MyTime = CLASS "PowerTime"
```

Once you have created a PowerTime object, you can manipulate it using the member methods. The IPowerTime interface is DUAL -- member methods may be referenced using either Direct or Dispatch form.

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime, Sign&, Years&, Months&, Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal

***Day&*)**

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

***ThisObject*.TimeDiff(*ThatObject*, *Sign&*, BYVAL *0*, BYVAL *0*, *Minutes&*)**

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&*

parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object.

The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

Example

PowerTime Object New!

Purpose A PowerTime Object contains a date and time value, allowing easy calculations. The internal representation emulates the Windows FILETIME structure as a quad-integer. This value represents the number of 100-nanosecond intervals since January 1, 1601. A nanosecond is one-billionth of a second.

You create a PowerTime object the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL MyTime AS IPowerTime
LET MyTime = CLASS "PowerTime"
```

Once you have created a PowerTime object, you can manipulate it using the member methods. The IPowerTime interface is DUAL -- member methods may be referenced using either Direct or Dispatch form.

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT

***Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)**

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

Example

PowerTime Object New!

Purpose A PowerTime Object contains a date and time value, allowing easy calculations. The internal representation emulates the Windows FILETIME structure as a quad-integer. This value represents the number of 100-nanosecond intervals since January 1, 1601. A nanosecond is one-billionth of a second.

You create a PowerTime object the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL MyTime AS IPowerTime
LET MyTime = CLASS "PowerTime"
```

Once you have created a PowerTime object, you can manipulate it using the member methods. The IPowerTime interface is DUAL -- member methods may be referenced using either Direct or Dispatch form.

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to

Minutes& (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

Example

PowerTime Object New!

Purpose A PowerTime Object contains a date and time value, allowing easy calculations. The internal representation emulates the Windows FILETIME structure as a quad-integer. This value represents the number of 100-nanosecond intervals since January 1, 1601. A nanosecond is one-billionth of a second.

You create a PowerTime object the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL MyTime AS IPowerTime
LET MyTime = CLASS "PowerTime"
```

Once you have created a PowerTime object, you can manipulate it using the member methods. The IPowerTime interface is DUAL -- member methods may be referenced using either Direct or Dispatch form.

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

`Today <38> ()`

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

`ToLocalTime <39> ()`

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

`ToUTC <40> ()`

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

`Year <42> () as Long`

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

Example

PowerTime Object New!

Purpose A PowerTime Object contains a date and time value, allowing easy calculations. The internal representation emulates the Windows FILETIME structure as a quad-integer. This value represents the number of 100-nanosecond intervals since January 1, 1601.   A nanosecond is one-billionth of a second.

You create a PowerTime object the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL MyTime AS IPowerTime
LET MyTime = CLASS "PowerTime"
```

Once you have created a PowerTime object, you can manipulate it using the member methods. The IPowerTime interface is DUAL -- member methods may be referenced using either Direct or Dispatch form.

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by

using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

Example

PowerTime Object New!

Purpose A PowerTime Object contains a date and time value, allowing easy calculations. The internal representation emulates the Windows FILETIME structure as a quad-integer. This value represents the number of 100-nanosecond intervals since January 1, 1601. A nanosecond is one-billionth of a second.

You create a PowerTime object the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL MyTime AS IPowerTime
LET MyTime = CLASS "PowerTime"
```

Once you have created a PowerTime object, you can manipulate it using the member methods. The IPowerTime interface is DUAL -- member methods may be referenced using either Direct or Dispatch form.

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
```

```
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

`ToUTC <40> ()`

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

`Year <42> () as Long`

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

`AddDays <1> (ByVal` ***`Days&`*****`)`**

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

`AddHours <2> (ByVal` ***`Hours&`*****`)`**

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the

PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

`TimeString <34> () AS String`

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

`TimeString24 <35> () AS WString`

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

`TimeStringFull <36> () AS WString`

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

`Today <38> ()`

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

`ToLocalTime <39> ()`

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

`ToUTC <40> ()`

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

`Year <42> () as Long`

Returns the Year component of the PowerTime object as a numeric value.

Example

PowerTime Object New!

Purpose A PowerTime Object contains a date and time value, allowing easy calculations. The internal representation emulates the Windows FILETIME structure as a quad-integer. This value represents the number of 100-nanosecond intervals since January 1, 1601.   A nanosecond is one-billionth of a second.

You create a PowerTime object the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL MyTime AS IPowerTime
LET MyTime = CLASS "PowerTime"
```

Once you have created a PowerTime object, you can manipulate it using the member methods. The IPowerTime interface is DUAL -- member methods may be referenced using either Direct or Dispatch form.

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the

PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal

***Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)**

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

Example

PowerTime Object New!

Purpose

A PowerTime Object contains a date and time value, allowing easy calculations. The internal representation emulates the Windows FILETIME structure as a quad-integer. This value represents the number of 100-nanosecond intervals since January 1, 1601. A nanosecond is one-billionth of a second.

You create a PowerTime object the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL MyTime AS IPowerTime
LET MyTime = CLASS "PowerTime"
```

Once you have created a PowerTime object, you can manipulate it using the member methods. The IPowerTime interface is DUAL -- member methods may be referenced using either Direct or Dispatch form.

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by

using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal

***Day&*)**

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

TimeString <34> () AS String

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

TimeString24 <35> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

TimeStringFull <36> () AS WString

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

Today <38> ()

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

ToLocalTime <39> ()

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

ToUTC <40> ()

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

Year <42> () as Long

Returns the Year component of the PowerTime object as a numeric value.

Example

PowerTime Object New!

Purpose

A PowerTime Object contains a date and time value, allowing easy calculations. The internal representation emulates the Windows FILETIME structure as a quad-integer. This value represents the number of 100-nanosecond intervals since January 1, 1601. A nanosecond is one-billionth of a second.

You create a PowerTime object the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL MyTime AS IPowerTime
LET MyTime = CLASS "PowerTime"
```

Once you have created a PowerTime object, you can manipulate it using the member methods. The IPowerTime interface is DUAL -- member methods may be referenced using either Direct or Dispatch form.

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

An immediate use for the PowerTime Object is the built-in numeric equate %PB_COMPILETIME. Each time you compile your program, this equate is filled with the current date and time of the compilation in PowerTime binary format. You can use the PowerTIME Class to convert it to a text equivalent for use in your application.

```
LOCAL Built AS IPowerTime
LET Built = CLASS "PowerTime"
Built.FileTime = %PB_COMPILETIME
MSGBOX  Built.DateString
MSGBOX  Built.TimeString
```

POWERTIME Methods

AddDays <1> (ByVal *Days&*)

Adds the specified number of days to the value of this object. You can subtract days by using a negative number.

AddHours <2> (ByVal *Hours&*)

Adds the specified number of hours to the value of this object. You can subtract hours by using a negative number.

AddMinutes <3> (ByVal *Minutes&*)

Adds the specified number of minutes to the value of this object. You can subtract minutes by using a negative number.

AddMonths <4> (ByVal *Months&*)

Adds the specified number of months to the value of this object. You can subtract months by using a negative number.

AddMSeconds <5> (ByVal *Milliseconds&*)

Adds the specified number of milliseconds to the value of this object. You can subtract milliseconds by using a negative number.

AddSeconds <6> (ByVal *Seconds&*)

Adds the specified number of seconds to the value of this object. You can subtract seconds by using a negative number.

AddTicks <7> (ByVal *Ticks&*)

Adds the specified number of ticks to the value of this object. You can subtract ticks by using a negative number.

AddYears <8> (ByVal *Years&*)

Adds the specified number of years to the value of this object. You can subtract years by using a negative number.

DateDiff <11> (*PowerTime*, *Sign&*, *Years&*, *Months&*, *Days&*)

The date part of the internal PowerTime object is compared to the date part of the specified external PowerTime object. The time-of-day part of each is ignored. The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. *Sign&* is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

DateString <12> (OPT ByVal *LCID&*) AS String

Returns the Date component of the PowerTime object expressed as a

. The date is formatted for the locale, based upon the *LCID&* parameter. If LCID& is zero, or not given, the default LCID for the user is substituted.

DateStringLong <13> (OPT ByVal *LCID&*) AS WString

Returns the Date component of the PowerTime object, expressed as a string, with a full alphabetic month name. The date is formatted for the locale, based upon the *LCID&* parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

Day <15> () AS Long

Returns the Day component of the PowerTime object. It is a

value in the range of 1-31.

DayOfWeek <16> () AS Long

Returns the Day-of-Week component of the PowerTime object. It is a numeric value in the range of 0-6 (representing Sunday through Saturday).

DayOfWeekString <17> (OPT ByVal *LCID&*) AS WString

Returns the Day-of-Week name of the PowerTime object, expressed as a string (Sunday, Monday...). The day name is appropriate for the locale, based upon the *LCID&*

parameter. If *LCID&* is zero, or not given, the default LCID for the user is substituted.

DaysInMonth <18> () AS Long

Returns the number of days which comprise the month of the date of the PowerTime object. This is a numeric value in the range of 28-31.

PROPERTY GET FileTime <20> () AS Quad

Returns a Quad-Integer value of the PowerTime object as a FileTime.

PROPERTY SET FileTime <20> (ByVal *FileTime&&*)

The FileTime Quad-Integer value specified by the parameter is assigned as the PowerTime object value.

Hour <21> () as Long

Returns the Hour component of the PowerTime object. It is a numeric value in the range of 0-23.

IsLeapYear <22> () as Long

Returns true/false (-1/0) to tell if the PowerTime object year is a leap year.

Minute <23> () as Long

Returns the Minute component of the PowerTime object. This is a numeric value in the range of 0-59.

Month <24> () as Long

Returns the Month component of the PowerTime object. This is a numeric value in the range of 1-12.

MonthString <25> () AS String

Returns the Month component of the PowerTime object, expressed as a string (January, February...).

MSecond <26> () as Long

Returns the millisecond component of the PowerTime object. This is a numeric value in the range of 0-999.

NewDate <27> (ByVal *Year&*, Opt ByVal *Month&*, Opt ByVal *Day&*)

The date component of the PowerTime object is assigned a new value based upon the specified parameters. The time component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

NewTime <28> (ByVal *Hour&*, Opt ByVal *Min&*, Opt ByVal *Sec&*, Opt ByVal *MSec&*, Opt ByVal *Tick&*)

The time component of the PowerTime object is assigned a new value based upon the specified parameters. The date component is unchanged. If parameters are invalid, an appropriate error code is returned in OBJRESULT.

Now <29> ()

The current local date and time on this computer is assigned to this PowerTime object.

NowUTC <30> ()

The current Coordinated Universal date and time (UTC) is assigned to this PowerTime object.

Second <31> () as Long

Returns the Second component of the PowerTime object. This is a numeric value in the range of 0-59.

Tick <32> () as Long

Returns the Tick component of the PowerTime object. This is a numeric value in the range of 0-999.

TimeDiff <33> (*PowerTime*, *Sign&*, *Days&*, OPT *Hours&*, OPT *Minutes&*, OPT *Seconds&*, OPT *MSeconds&&*, OPT *Ticks&&*)

The internal PowerTime object is compared to the specified external PowerTime object.

The difference is assigned to the parameter variables you provide. *Sign&* is -1 if the internal value is smaller. *Sign&* is 0 if the values are equal. Sign is +1 if the internal value is larger. The other parameters tell the difference as positive integer values. If you wish to return the time difference in units smaller than days, fill the unwanted parameters with BYVAL 0 and they will be ignored. For example:

```
ThisObject.TimeDiff(ThatObject, Sign&, BYVAL 0, BYVAL 0, Minutes&)
```

In the above, if the difference was precisely one day, the value 1440 would be assigned to *Minutes&* (24 hours * 60 minutes). If parameters are invalid, an appropriate error code is returned in OBJRESULT.

`TimeString <34> () AS String`

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm AM/PM.

`TimeString24 <35> () AS WString`

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm in 24-hour notation.

`TimeStringFull <36> () AS WString`

Returns the Time component of the PowerTime object expressed as a string. The time is formatted as hh:mm:ss.mmm in 24-hour notation.

`Today <38> ()`

The current local date on this computer is assigned to this PowerTime object. This is suitable for applications that work with dates only.

`ToLocalTime <39> ()`

The PowerTime object is converted to local time. It is assumed that the previous value was in Coordinated Universal Time (UTC).

`ToUTC <40> ()`

The PowerTime object is converted to Coordinated Universal Time (UTC). It is assumed that previous value was in local time.

`Year <42> () as Long`

Returns the Year component of the PowerTime object as a numeric value.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the

OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax *The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

`COUNT <2> AS Long`

The number of data items currently contained in the QueueCollection is returned to the caller.

`DEQUEUE <3> AS Variant`

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`ENQUEUE <4> (PowerItem AS Variant)`

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose

A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax *The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose

A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

`REMOVE <11> (`*`Index`*` AS Long)`

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`REPLACE <12> (Index AS Long, PowerItem AS Variant)`

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

`CLEAR <1>`

All *PowerItems* are removed from the StackCollection.

`COUNT <2> AS Long`

The number of data items currently contained in the StackCollection is returned to the caller.

`POP <3> AS Variant`

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`PUSH <4> (PowerItem AS Variant)`

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection

A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax

The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

`CLEAR <1>`

All *PowerItems* are removed from the QueueCollection.

`COUNT <2> AS Long`

The number of data items currently contained in the QueueCollection is returned to the

caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the

same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax *The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

```
IndexVar& = ObjectVar.INDEX(0)
```

The above example retrieves the current index number, without changing it, and assigns it

to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL

interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose

A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as

either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

IndexVar& **=** ***ObjectVar*****.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved

sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If

the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may

be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

[LET] *VrntVar* = *TypeVar* AS STRING

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

***CollObj*.Add(*Key$$*, *UDTVar* AS STRING)**

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position

number, or sequentially in ascending or descending sequence.

Syntax *The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).*

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**
<*ObjectVar*>.membername(*params*) TO *ReturnVariable*

Remarks Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is

successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection

A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax

The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

COLLECTION Object Group New!

Purpose

A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should

be limited to PowerBASIC applications.

Power Collection A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax *The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

FIRST <1> AS Long

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <8> (*Index* AS Long) AS Long

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

ITEM <9> (*PowerKey* AS WString) AS Variant

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <10> AS Long

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <11> AS Variant

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <12> (*PowerKey* AS WString)

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <13> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

SORT <14> (*Flags* AS Long)

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the

caller.

`FIRST <1> AS Long`

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

<*ObjectVar*>.membername(*params*)
***RetVal* = <*ObjectVar*>.membername(*params*)**

```
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax *The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).*

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

Example

STRINGBUILDER Object New!

Purpose The StringBuilder object offers the ability to concatenate many sections at a very high level of performance. The speed of execution is particularly noticeable when the concatenation is performed in many separate operations over a period of time. If all of the string sections are known and available at once, the use of the BUILD$() function could be a better choice. However, both options offer a very large boost as compared to the standard concatenation operators (& or +). In addition to concatenation, the StringBuilder Class also offers a few additional string operations to assist in building the string.

Remarks There are two forms of the StringBuilder object, one for ANSI strings, and one for WIDE (Unicode) strings. While they could have been combined into a single hybrid object, that would have added additional overhead not acceptable for PowerBASIC. To concatenate ANSI strings, use the StringBuilderA class and the IStringBuilderA interface. To concatenate WIDE (Unicode) strings, use the StringBuilderW class and the IStringBuilderW interface. The methods and mode of operation are identical for both forms.

If you choose the ANSI form, parameter strings must be ANSI, and result strings will be ANSI. With the WIDE (Unicode) form, parameter strings must be wide, and result strings will be wide. Keep those requirements in mind when reviewing the following method definitions. The Dispatch ID (DispID) for each member method is displayed within angle brackets.

When you create a StringBuilder object, a dynamic string buffer is created to hold the target string. If you know the size of the result string (or even an approximation), it's usually prudent to use the CAPACITY method first, to establish a size at least as large as the final string. If it's not known, PowerBASIC will try to make appropriate decisions for you. Once the object is created, the ADD method is used to append string sections as many times as necessary. Finally, the STRING method is used to extract the combined items.

StringBuilder Methods/Properties

ADD (*PowerString$*) **Method<1>**

The *PowerString$* parameter is appended to the string held in the StringBuilder object. If the internal string buffer overflows, PowerBASIC will automatically extend it to an appropriate size. If a necessary buffer extension fails, an HResult of E_OUTOFMEMORY (&H8007000E) is returned, and an Object Error (99) is generated.

CAPACITY () AS Long **Get Property<2>**

The size of the internal string buffer is retrieved and returned to the caller. The size is the number of characters which can be stored without further expansion.

CAPACITY () = Long **Set Property<2>**

The internal string buffer is expanded to the number of characters specified by the Long Integer. If the new capacity is smaller or equal to the current capacity, no operation is performed.

CHAR (*Index&*) AS Long **Get Property<3>**

The numeric character code of the character at the position *Index&* is retrieved and returned to the caller. Index&=1 for the first character, 2 for the second, etc. If *Index&* is beyond the current length of the string, the value -1 is returned.

CHAR (*Index&*) = Long **Set Property<3>**

The character at the position *Index&* is changed to that specified by the Long Integer character code. *Index&*=1 for the first character, 2 for the second, etc.

CLEAR **Method<4>**

All data in the object is erased.

DELETE (*Index&, Count&*) **Method<5>**

Count& characters are removed starting at the position given by *Index&*. *Index&*=1 for the first character, 2 for the second, etc.

INSERT (*PowerString$, Index&*) **Method<6>**

The *PowerString$* parameter is inserted in the string starting at the position given by *Index&*. *Index&*=1 for the first character, 2 for the second, etc. If *Index&* is beyond the current length of the string, no operation is performed.

LEN () AS Long **Method<7>**

The number of characters currently stored in the object is returned as a long integer value.

STRING AS String **Method<8>**

The string stored in the object is returned to the caller. This string will contain LEN characters.

Example

STRINGBUILDER Object New!

Purpose The StringBuilder object offers the ability to concatenate many sections at a very high level of performance. The speed of execution is particularly noticeable when the concatenation is performed in many separate operations over a period of time. If all of the string sections are known and available at once, the use of the BUILD$() function could be a better choice. However, both options offer a very large boost as compared to the standard concatenation operators (& or +). In addition to concatenation, the StringBuilder Class also offers a few additional string operations to assist in building the string.

Remarks There are two forms of the StringBuilder object, one for ANSI strings, and one for WIDE (Unicode) strings. While they could have been combined into a single hybrid object, that would have added additional overhead not acceptable for PowerBASIC. To concatenate ANSI strings, use the StringBuilderA class and the IStringBuilderA interface. To concatenate WIDE (Unicode) strings, use the StringBuilderW class and the IStringBuilderW interface. The methods and mode of operation are identical for both forms.

If you choose the ANSI form, parameter strings must be ANSI, and result strings will be ANSI. With the WIDE (Unicode) form, parameter strings must be wide, and result strings will be wide. Keep those requirements in mind when reviewing the following method definitions. The Dispatch ID (DispID) for each member method is displayed within angle brackets.

When you create a StringBuilder object, a dynamic string buffer is created to hold the target string. If you know the size of the result string (or even an approximation), it's usually prudent to use the CAPACITY method first, to establish a size at least as large as the final string. If it's not known, PowerBASIC will try to make appropriate decisions for you. Once the object is created, the ADD method is used to append string sections as many times as necessary. Finally, the STRING method is used to extract the combined items.

StringBuilder Methods/Properties

`ADD (`*`PowerString$`*`)` **`Method<1>`**

The *PowerString$* parameter is appended to the string held in the StringBuilder object. If the internal string buffer overflows, PowerBASIC will automatically extend it to an appropriate size. If a necessary buffer extension fails, an HResult of E_OUTOFMEMORY (&H8007000E) is returned, and an Object Error (99) is generated.

`CAPACITY () AS Long` **`Get Property<2>`**

The size of the internal string buffer is retrieved and returned to the caller. The size is the number of characters which can be stored without further expansion.

`CAPACITY () = Long` **`Set Property<2>`**

The internal string buffer is expanded to the number of characters specified by the Long Integer. If the new capacity is smaller or equal to the current capacity, no operation is performed.

`CHAR (`*`Index&`*`) AS Long` **`Get Property<3>`**

The numeric character code of the character at the position *Index&* is retrieved and returned to the caller. Index&=1 for the first character, 2 for the second, etc. If *Index&* is beyond the current length of the string, the value -1 is returned.

`CHAR (`*`Index&`*`) = Long` **`Set Property<3>`**

The character at the position *Index&* is changed to that specified by the Long Integer character code. *Index&*=1 for the first character, 2 for the second, etc.

`CLEAR` **`Method<4>`**

All data in the object is erased.

`DELETE (`*`Index&, Count&`*`)` **`Method<5>`**

Count& characters are removed starting at the position given by *Index&*. *Index&*=1 for the first character, 2 for the second, etc.

`INSERT (`*`PowerString$, Index&`*`)` **`Method<6>`**

The *PowerString$* parameter is inserted in the string starting at the position given by *Index&*. *Index&*=1 for the first character, 2 for the second, etc. If *Index&* is beyond the current length of the string, no operation is performed.

`LEN () AS Long` **`Method<7>`**

The number of characters currently stored in the object is returned as a long integer value.

`STRING AS String` **`Method<8>`**

The string stored in the object is returned to the caller. This string will contain LEN characters.

The internal string buffer is expanded to the number of characters specified by the Long Integer. If the new capacity is smaller or equal to the current capacity, no operation is performed.

CHAR (*Index&*) AS Long **Get Property<3>**

The numeric character code of the character at the position *Index&* is retrieved and returned to the caller. Index&=1 for the first character, 2 for the second, etc. If *Index&* is beyond the current length of the string, the value -1 is returned.

CHAR (*Index&*) = Long **Set Property<3>**

The character at the position *Index&* is changed to that specified by the Long Integer character code. *Index&*=1 for the first character, 2 for the second, etc.

CLEAR **Method<4>**

All data in the object is erased.

DELETE (*Index&, Count&*) **Method<5>**

Count& characters are removed starting at the position given by *Index&*. *Index&*=1 for the first character, 2 for the second, etc.

INSERT (*PowerString$, Index&*) **Method<6>**

The *PowerString$* parameter is inserted in the string starting at the position given by *Index&*. *Index&*=1 for the first character, 2 for the second, etc. If *Index&* is beyond the current length of the string, no operation is performed.

LEN () AS Long **Method<7>**

The number of characters currently stored in the object is returned as a long integer value.

STRING AS String **Method<8>**

The string stored in the object is returned to the caller. This string will contain LEN characters.

Example

STRINGBUILDER Object New!

Purpose The StringBuilder object offers the ability to concatenate many sections at a very high level of performance. The speed of execution is particularly noticeable when the concatenation is performed in many separate operations over a period of time. If all of the string sections are known and available at once, the use of the BUILD$() function could be a better choice. However, both options offer a very large boost as compared to the standard concatenation operators (& or +). In addition to concatenation, the StringBuilder Class also offers a few additional string operations to assist in building the string.

Remarks There are two forms of the StringBuilder object, one for ANSI strings, and one for WIDE (Unicode) strings. While they could have been combined into a single hybrid object, that would have added additional overhead not acceptable for PowerBASIC. To concatenate ANSI strings, use the StringBuilderA class and the IStringBuilderA interface. To concatenate WIDE (Unicode) strings, use the StringBuilderW class and the IStringBuilderW interface. The methods and mode of operation are identical for both forms.

If you choose the ANSI form, parameter strings must be ANSI, and result strings will be ANSI. With the WIDE (Unicode) form, parameter strings must be wide, and result strings will be wide. Keep those requirements in mind when reviewing the following method definitions. The Dispatch ID (DispID) for each member method is displayed within angle brackets.

When you create a StringBuilder object, a dynamic string buffer is created to hold the target string. If you know the size of the result string (or even an approximation), it's

usually prudent to use the CAPACITY method first, to establish a size at least as large as the final string. If it's not known, PowerBASIC will try to make appropriate decisions for you. Once the object is created, the ADD method is used to append string sections as many times as necessary. Finally, the STRING method is used to extract the combined items.

StringBuilder Methods/Properties

ADD (*PowerString$*) — **Method<1>**

The *PowerString$* parameter is appended to the string held in the StringBuilder object. If the internal string buffer overflows, PowerBASIC will automatically extend it to an appropriate size. If a necessary buffer extension fails, an HResult of E_OUTOFMEMORY (&H8007000E) is returned, and an Object Error (99) is generated.

CAPACITY () AS Long — **Get Property<2>**

The size of the internal string buffer is retrieved and returned to the caller. The size is the number of characters which can be stored without further expansion.

CAPACITY () = Long — **Set Property<2>**

The internal string buffer is expanded to the number of characters specified by the Long Integer. If the new capacity is smaller or equal to the current capacity, no operation is performed.

CHAR (*Index&*) AS Long — **Get Property<3>**

The numeric character code of the character at the position *Index&* is retrieved and returned to the caller. Index&=1 for the first character, 2 for the second, etc. If *Index&* is beyond the current length of the string, the value -1 is returned.

CHAR (*Index&*) = Long — **Set Property<3>**

The character at the position *Index&* is changed to that specified by the Long Integer character code. *Index&*=1 for the first character, 2 for the second, etc.

CLEAR — **Method<4>**

All data in the object is erased.

DELETE (*Index&, Count&*) — **Method<5>**

Count& characters are removed starting at the position given by *Index&*. *Index&*=1 for the first character, 2 for the second, etc.

INSERT (*PowerString$, Index&*) — **Method<6>**

The *PowerString$* parameter is inserted in the string starting at the position given by *Index&*. *Index&*=1 for the first character, 2 for the second, etc. If *Index&* is beyond the current length of the string, no operation is performed.

LEN () AS Long — **Method<7>**

The number of characters currently stored in the object is returned as a long integer value.

STRING AS String — **Method<8>**

The string stored in the object is returned to the caller. This string will contain LEN characters.

StringBuilder Methods/Properties

ADD (*PowerString$*) **Method<1>**

The *PowerString$* parameter is appended to the string held in the StringBuilder object. If the internal string buffer overflows, PowerBASIC will automatically extend it to an appropriate size. If a necessary buffer extension fails, an HResult of E_OUTOFMEMORY (&H8007000E) is returned, and an Object Error (99) is generated.

CAPACITY () AS Long **Get Property<2>**

The size of the internal string buffer is retrieved and returned to the caller. The size is the number of characters which can be stored without further expansion.

CAPACITY () = Long **Set Property<2>**

The internal string buffer is expanded to the number of characters specified by the Long Integer. If the new capacity is smaller or equal to the current capacity, no operation is performed.

CHAR (*Index&*) AS Long **Get Property<3>**

The numeric character code of the character at the position *Index&* is retrieved and returned to the caller. Index&=1 for the first character, 2 for the second, etc. If *Index&* is beyond the current length of the string, the value -1 is returned.

CHAR (*Index&*) = Long **Set Property<3>**

The character at the position *Index&* is changed to that specified by the Long Integer character code. *Index&*=1 for the first character, 2 for the second, etc.

CLEAR **Method<4>**

All data in the object is erased.

DELETE (*Index&, Count&*) **Method<5>**

Count& characters are removed starting at the position given by *Index&*. *Index&*=1 for the first character, 2 for the second, etc.

INSERT (*PowerString$, Index&*) **Method<6>**

The *PowerString$* parameter is inserted in the string starting at the position given by *Index&*. *Index&*=1 for the first character, 2 for the second, etc. If *Index&* is beyond the current length of the string, no operation is performed.

LEN () AS Long **Method<7>**

The number of characters currently stored in the object is returned as a long integer value.

STRING AS String **Method<8>**

The string stored in the object is returned to the caller. This string will contain LEN characters.

STRINGBUILDER Object New!

Purpose The StringBuilder object offers the ability to concatenate many sections at a very high level of performance. The speed of execution is particularly noticeable when the concatenation is performed in many separate operations over a period of time. If all of the string sections are known and available at once, the use of the BUILD$() function could be a better choice. However, both options offer a very large boost as compared to the standard concatenation operators (& or +). In addition to concatenation, the StringBuilder Class also offers a few additional string operations to assist in building the string.

Remarks There are two forms of the StringBuilder object, one for ANSI strings, and one for WIDE (Unicode) strings. While they could have been combined into a single hybrid object, that would have added additional overhead not acceptable for PowerBASIC. To concatenate ANSI strings, use the StringBuilderA class and the IStringBuilderA interface. To concatenate WIDE (Unicode) strings, use the StringBuilderW class and the IStringBuilderW interface. The methods and mode of operation are identical for both forms.

If you choose the ANSI form, parameter strings must be ANSI, and result strings will be ANSI. With the WIDE (Unicode) form, parameter strings must be wide, and result strings will be wide. Keep those requirements in mind when reviewing the following method definitions. The Dispatch ID (DispID) for each member method is displayed within angle brackets.

When you create a StringBuilder object, a dynamic string buffer is created to hold the target string. If you know the size of the result string (or even an approximation), it's

usually prudent to use the CAPACITY method first, to establish a size at least as large as the final string. If it's not known, PowerBASIC will try to make appropriate decisions for you. Once the object is created, the ADD method is used to append string sections as many times as necessary. Finally, the STRING method is used to extract the combined items.

StringBuilder Methods/Properties

ADD (*PowerString$*) **Method<1>**

The *PowerString$* parameter is appended to the string held in the StringBuilder object. If the internal string buffer overflows, PowerBASIC will automatically extend it to an appropriate size. If a necessary buffer extension fails, an HResult of E_OUTOFMEMORY (&H8007000E) is returned, and an Object Error (99) is generated.

CAPACITY () AS Long **Get Property<2>**

The size of the internal string buffer is retrieved and returned to the caller. The size is the number of characters which can be stored without further expansion.

CAPACITY () = Long **Set Property<2>**

The internal string buffer is expanded to the number of characters specified by the Long Integer. If the new capacity is smaller or equal to the current capacity, no operation is performed.

ISFALSE operator

ISFALSE and ISTRUE operators

Purpose Return the logical truth or falsity of a given expression.

Syntax

```
ISFALSE expr
ISTRUE expr
```

Remarks ISTRUE returns -1 (TRUE) when expr evaluates as non-zero; otherwise, it returns zero

(FALSE). ISFALSE returns -1 when expr evaluates as 0 (FALSE); otherwise, it returns zero.

Truth table

operator	***expr***	**Result**
ISTRUE	= 0	0
ISTRUE	<> 0	-1
ISFALSE	= 0	-1
ISFALSE	<> 0	0

PowerBASIC's NOT operator serves a double duty: it returns the one's-complement of an expression and "reverses" the value of a TRUE/FALSE (Boolean) expression. Usually, these two functions do not conflict, but since PowerBASIC accepts any non-zero value as TRUE, the following condition can arise:

```
test1 = 0           ' test1 is FALSE (zero)
IF NOT test1 THEN   ' TRUE (-1 is non-zero)
[statements]

test2 = 1           ' test2 is TRUE (1 is non-zero)
IF NOT test2 THEN   ' still TRUE (-2 is non-zero)
[statements]
```

In this case, NOT does not reverse the TRUE/FALSE value of test2. ISFALSE ensures that the test is performed exactly as you would expect:
test2 = 1 ' test2 is TRUE (non-zero)

```
IF ISFALSE test2 THEN ' ISFALSE detects test2 is
[statements]          ' TRUE so the IF test fails
```

This problem does not exist when you're testing for logical truth. PowerBASIC considers that an expression is TRUE in every case *except* when the expression is zero. However, ISTRUE converts all non-zero values to the "most true" value, -1, which provides the most consistent results with both boolean and arithmetic expressions.

Restrictions ISTRUE and ISFALSE operators evaluate the "whole" expression following the keyword, subject to their Operator Precedence level. For example, parentheses contained within the expression are regarded as an integral part of the expression, and do not act as delimiters for the ISTRUE and ISFALSE operators.

With this in mind, combining a logical test result into a further expression means that the expressions must be separated to ensure the correct evaluation.

Consider the following statement:

```
IF ISTRUE (x&) + y& THEN
```

PowerBASIC evaluates the entire expression *(x&) + y&* and then calculates the logical truth from the overall result of that expression. That is, the parentheses around the first part of the expression do not stop ISTRUE from evaluating the whole expression. To demonstrate this, the statement can be rewritten to concisely demonstrate the scope of the logical evaluation:

```
IF ISTRUE (x& + 2) THEN
```

or it could be simplified even further:

```
IF ISTRUE x& + 2 THEN
```

If you wish to utilize the numeric result of the logical test in a further expression, parentheses must be added to separate the expressions correctly:

```
IF (ISTRUE x&) + 2 THEN
```

See also Arithmetic Operators, NOT, Short-circuit evaluation

ISFILE Function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

ISFILE Function

Purpose	Determine whether or not a file exists.
Syntax	***FileExists&* = ISFILE(*FileName*)**
Remarks	The file subsystem is checked to determine whether the file specified by *FileName* currently exists. If it is found in any form (hidden, system, read-only, etc.), the value true (-1) is returned. Otherwise, the value false (0) is returned. *Filename* is an unambiguous file name, which may not contain an asterisk (*) or query (?). If it contains one or more of those characters, the function always returns false (0).
See also	DIR$, DISPLAY BROWSE, DISPLAY OPENFILE, DISPLAY SAVEFILE, ISFOLDER, PATHSCAN$

ISFOLDER function

ISFOLDER function

Purpose	Determine whether or not a folder exists.
Syntax	***FolderExists&* = ISFOLDER(*FolderName*)**
Remarks	The file subsystem is checked to determine whether the folder specified by *FolderName* currently exists. If it is found in any form (hidden, system, read-only, etc.), the value true (-1) is returned. Otherwise, the value false (0) is returned. The root directory (for example, "C:\") is considered to be a folder, and returns the value true (-1). *FolderName* is an unambiguous file name, which may not contain an asterisk (*) or query (?). If it contains one or more of those characters, the function always returns false (0).
See also	DIR$, DISPLAY BROWSE, DISPLAY OPENFILE, DISPLAY SAVEFILE, ISFILE, PATHSCAN$

ISINTERFACE Function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

ISINTERFACE Function

Purpose Determine whether an object supports a particular interface.

Syntax `IfaceValid = ISINTERFACE(ObjectVar, InterfaceName)`

Remarks The object referenced by the parameter *ObjectVar* is tested to determine if the specified *InterfaceName* is supported. If so, the value true (-1) is returned. Otherwise, the value false (0) is returned.

See also CLASS, INTERFACE (Direct), INTERFACE (IDBind), What is an object, anyway?

ISMISSING function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

ISMISSING function

Purpose Determine whether an

was passed by the calling code.

Syntax `ParamStatus = ISMISSING(ParamVar)`

Remarks The ISMISSING function may be used to test certain optional parameters to determine whether or not the parameter was actually passed by the calling code. It may be used to test

VARIANT parameters, or other variable types passed ByRef. An attempt to test a ByVAL parameter other than VARIANT will generate an error 579 (BYREF variable or BYVAL/BYREF variant expected) to be generated during compilation.

A ByRef parameter is considered to be missing when the pointer has the value zero. A variant parameter is considered to be missing when it has a type of %VT_ERROR and an error value of %DISP_E_PARAMNOTFOUND.

If the specified optional parameter is missing, the value true (-1) is returned. Otherwise, the value false (0) is returned.

Restrictions The ISMISSING function may only be used within the procedure which uses the specified optional parameter.

See also DECLARE, FUNCTION, METHOD, PROPERTY, SUB

ISNOTHING function

ISNOTHING function

Purpose Determine the current status of a given object variable.

Syntax `oStatus = ISNOTHING(objectvar)`

Remarks ISNOTHING is particularly useful in determining the success or failure of a LET statement. It returns TRUE (-1) if the object variable contains nothing, or FALSE (0) if it contains a valid current reference to an object interface.

ISNOTHING is the complement to the ISOBJECT function.

Restrictions *objectvar* must be an
or IDispatch object variable.

See also DIM, INTERFACE (Direct), INTERFACE (IDBind), ISOBJECT, LET (with Objects), OBJECT, What is an object, anyway?

Example

```
DIM oApp AS IAPPDatabase
LET oApp = NEW IAPPDatabase IN "DBApp.0"
IF ISNOTHING(oApp) OR ERR THEN ' Handle error
```

ISNOTNULL function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

ISNOTNULL function New!

Purpose Determine if a
is not null (contains 1 or more characters).

Syntax `ResultVar& = ISNOTNULL(StrgExpr)`

Remarks The *StrgExpr* is examined to determine if it is null, or if it contains one or more characters. The value true (-1) is returned if the *StrgExpr* contains characters, or false (0) if it is null (zero-length).

The complementary function is ISNULL.

See also ISNULL

ISNULL function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

ISNULL function New!

Purpose Determine if a
is null (zero-length).

Syntax `ResultVar& = ISNULL(StrgExpr)`

Remarks The *StrgExpr* is examined to determine whether it is null (has zero characters). The value true (-1) is returned if the *StrgExpr* is null, or false (0) if it contains characters.

The complementary function is ISNOTNULL.

See also ISNOTNULL

ISOBJECT function

ISOBJECT function

Purpose Determine the current status of a given object variable.

Syntax `oStatus = ISOBJECT(objectvar)`

Remarks ISOBJECT is particularly useful in determining the success or failure of a LET (with Objects) statement. It returns TRUE (-1) if the object variable contains a valid current reference to an object interface, or FALSE (0) if it contains nothing.

ISOBJECT is the complement to the ISNOTHING function.

Restrictions *objectvar* must be an

or IDispatch object variable.

See also DIM, INTERFACE (Direct), INTERFACE (IDBind), ISNOTHING, LET (with Objects), OBJECT, What is an object, anyway?

Example

```
DIM oApp AS IAPPDatabase
LET oApp = NEWCOM "DBApp.0"
IF ISOBJECT(oApp) AND ISFALSE ERR THEN 'Handle error
```

IStackCollection

Keyword Template

Purpose

Syntax

Remarks

Example

COLLECTION Object Group New!

Purpose A collection object is a set of items which can be referred to as a unit. It provides a convenient way to refer to a related group of items as a single object. The items in a collection need only be related by the fact that they exist in the collection. They do not have to share the same data type.

You create a collection the same way you create other objects, but using a predefined internal class and a predefined internal interface.

```
LOCAL Collect AS IPowerCollection
LET Collect = CLASS "PowerCollection"
```

Once you have created a collection object, you can manipulate it using the member methods. Each data item in the set is stored as a variant variable, which may contain any valid data type (

, string, UDT, object, etc.). Collection interfaces are DUAL -- member methods may be referenced using either Direct or Dispatch form.

While the collection object expects to receive your data items as variant variables, you can take advantage of the auto-conversion options in PowerBASIC. If a variant parameter is expected, and you pass a single variable instead, PowerBASIC will automatically convert it with no intervention needed on your part.

Very often, it's convenient to create a collection of user defined types (UDT). While a variant may not normally contain a UDT, PowerBASIC offers a special methodology to do so. At programmer direction, a TYPE may be assigned to a variant (as a byte string) by using:

```
[LET] VrntVar = TypeVar AS STRING
```

In the same manner, a UDT argument can be auto-converted to the variant type by appending AS STRING:

```
CollObj.Add(Key$$, UDTVar AS STRING)
```

The data contained in the User-Defined Type variable (UDTVar) is stored in the variant argument as a dynamic string of bytes (vt_bstr). When the collection object retrieves that UDT data, it understands the content and handles it accurately. This special technique offers ease of coding and much improved execution speed. If you like, you can use the same sort of functionality in your own PowerBASIC code. However, you should keep in mind that other programming languages may not understand this technique, so it should be limited to PowerBASIC applications.

Power Collection

A Power Collection creates a set of data items, each of which is associated with an alpha-numeric

key which you define. The data item is passed and stored as a variant, while the key is passed and stored as a wide (Unicode) string. You can retrieve these data items directly by using their key, by their position in the collection, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "PowerCollection". The INTERFACE is IPowerCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

Items in a PowerCollection may be retrieved by their key using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS method. Each key in a PowerCollection must be unique. Keys in a PowerCollection are case-sensitive. To access the keys in a case-insensitive manner, you must create and retrieve all keys as either upper case or lower case, but not mixed.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Power Collection Methods

ADD <3> (*PowerKey* AS WString, *PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the PowerCollection. It is associated with the *PowerKey* string for later retrieval. If the operation was successful, an HResult of S_OK (0) is returned. If it fails because of a duplicate key, an HResult of E_DUPLICATEKEY (&H800A01C9) is returned, and an Object Error (99) is generated.

CLEAR <4>

All *PowerKeys* and *PowerItems* are removed from the PowerCollection.

CONTAINS <5> (*PowerKey* AS WString) AS Long

The PowerCollection is scanned to determine if the specified *PowerKey* is present. If found, the Index number of this Item (range of 1 - COUNT) is returned. This value will always evaluate as true. If not found, the value false (0) is returned.

COUNT <6> AS Long

The number of data items currently contained in the PowerCollection is returned to the caller.

ENTRY <7> (*Index* AS Long, OUT *PowerKey* as WString, OUT *PowerItem* as Variant)

The PowerCollection entry specified by the *Index* number is returned to the caller in the two specified OUT parameters. If the index number is less than one, or greater than the item count, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`FIRST <1> AS Long`

The current INDEX for the PowerCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

`INDEX <8> (Index AS Long) AS Long`

The current INDEX for the PowerCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than the current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

```
IndexVar& = ObjectVar.INDEX(0)
```

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

`ITEM <9> (PowerKey AS WString) AS Variant`

The *PowerItem* associated with the specified *PowerKey* is returned. If the specified key is not found, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

`LAST <10> AS Long`

The current INDEX for the PowerCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

`NEXT <2> AS Variant`

The NEXT method allows the PowerCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

`PREVIOUS <11> AS Variant`

The PREVIOUS method allows the PowerCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

`REMOVE <12> (PowerKey AS WString)`

The specified *PowerKey*, and the *PowerItem* associated with it, are removed from the PowerCollection. The index number of each data item past the removed item is decremented by one. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`REPLACE <13> (PowerKey AS WString, PowerItem AS Variant)`

The *PowerItem* associated with the specified *PowerKey* is replaced by the new specified *PowerItem*. If the requested *PowerKey* is not found, OBJRESULT returns %S_FALSE (1) and no operation is performed.

`SORT <14> (Flags AS Long)`

The data items in the PowerCollection are sorted based upon the text in the associated *PowerKeys*. If the parameter Flags is zero(0), the items are sorted in ascending sequence. If one (1), the items are sorted in descending sequence.

LinkList Collection

A Linked List Collection is an ordered set of data items, which are accessed by their position in the list rather than by an alphanumeric string key. Each data item is passed and stored as a variant variable. You can retrieve these data items by their position number, or sequentially in ascending or descending sequence.

Syntax

The CLASS is "LinkListCollection". The INTERFACE is ILinkListCollection (a DUAL

interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks Items in a LinkListCollection may be retrieved by their position number using the ITEM method. They may be retrieved sequentially using the NEXT or PREVIOUS methods.

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

LinkList Collection Methods

ADD <3> (*PowerItem* AS Variant)

The *PowerItem* variant is added to the end of the LinkListCollection.

CLEAR <4>

All *PowerItems* are removed from the LinkListCollection.

COUNT <5> AS Long

The number of data items currently contained in the LinkListCollection is returned to the caller.

FIRST <1> AS Long

The current INDEX for the LinkListCOLLECTION is set to one (1), so that subsequent references to the NEXT method will access member items from the beginning. The previous value of the INDEX is returned to the caller.

INDEX <6> (*Index* AS Long) AS Long

The current INDEX for the LinkListCOLLECTION is set to the specified *index* number. If the parameter is less than one, or greater than current count of data items, the INDEX is not changed. The previous value of the INDEX is returned to the caller.

***IndexVar&* = *ObjectVar*.INDEX(0)**

The above example retrieves the current index number, without changing it, and assigns it to the variable *IndexVar&*.

INSERT <7> (*Index* AS Long, *PowerItem* AS Variant)

The *PowerItem* variant is added to the collection at the position specified by the *Index*. If the index number is less than one, or greater than the count, the item is added to the end of the list.

ITEM <8> (*Index* AS Long) AS Variant

The *PowerItem* at the position specified by *Index* is returned. If the specified item is not present, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

LAST <9> AS Long

The current INDEX for the LinkListCOLLECTION is set to the last item so that subsequent references to the PREVIOUS method will access member items from the end. The previous value of the INDEX is returned to the caller.

NEXT <2> AS Variant

The NEXT method allows the LinkListCollection data items to be retrieved sequentially. Each time NEXT is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is incremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

PREVIOUS <10> AS Variant

The PREVIOUS method allows the LinkListCollection data items to be retrieved sequentially. Each time PREVIOUS is referenced, the data item at the position specified by the INDEX is returned to the caller, and the INDEX is decremented. If the operation is successful, the OBJRESULT is set to %S_OK (0). When there are no more data items to retrieve, the OBJRESULT is set to %S_FALSE (1).

REMOVE <11> (*Index* AS Long)

The *PowerItem* at the position specified by *Index* is removed from the LinkListCollection. The index number of each data item past the removed item is decremented by one. If the requested item is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

REPLACE <12> (Index AS Long, PowerItem AS Variant)

The *PowerItem* at the position specified by *Index* is replaced by the new specified *PowerItem*. If the requested *PowerItem* is not present, OBJRESULT returns %S_FALSE (1) and no operation is performed.

Stack Collection

A Stack Collection is an ordered set of data items, which are accessed on a LIFO (Last-In / First-Out) basis. This collection follows the same algorithm as the machine stack on your Intel CPU. Each data item is passed and stored as a variant variable, using the PUSH and POP methods.

Syntax

The CLASS is "StackCollection". The INTERFACE is IStackCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Stack Collection Methods

CLEAR <1>

All *PowerItems* are removed from the StackCollection.

COUNT <2> AS Long

The number of data items currently contained in the StackCollection is returned to the caller.

POP <3> AS Variant

The *PowerItem* at the "Stack-Top" (the item most recently added) is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

PUSH <4> (PowerItem AS Variant)

The specified *PowerItem* is added to the StackCollection at the "Stack-Top" position.

Queue Collection

A Queue Collection is an ordered set of data items, which are accessed on a FIFO (First-In / First-Out) basis. Each data item is passed and stored as a variant variable, using the ENQUEUE and DEQUEUE methods.

Syntax

The CLASS is "QueueCollection". The INTERFACE is IQueueCollection (a DUAL interface).

```
<ObjectVar>.membername(params)
RetVal = <ObjectVar>.membername(params)
<ObjectVar>.membername(params) TO ReturnVariable
```

Remarks

The Dispatch ID (DispID) for each member method is displayed within angle brackets.

Queue Collection Methods

CLEAR <1>

All *PowerItems* are removed from the QueueCollection.

COUNT <2> AS Long

The number of data items currently contained in the QueueCollection is returned to the caller.

DEQUEUE <3> AS Variant

The *PowerItem* at the "oldest" position is retrieved and returned to the caller. When there are no more data items to retrieve, the variant returned will be of type empty (VT_EMPTY), and the OBJRESULT will be %S_FALSE (1).

ENQUEUE <4> (*PowerItem* AS Variant)

The specified *PowerItem* is added to the QueueCollection at the "newest" position.

See Also FOR EACH/NEXT

ISTRUE operator

ISFALSE and ISTRUE operators

Purpose Return the logical truth or falsity of a given expression.

Syntax

```
ISFALSE expr
ISTRUE expr
```

Remarks ISTRUE returns -1 (TRUE) when expr evaluates as non-zero; otherwise, it returns zero (FALSE). ISFALSE returns -1 when expr evaluates as 0 (FALSE); otherwise, it returns zero.

Truth table

operator	*expr*	Result
ISTRUE	= 0	0
ISTRUE	<> 0	-1
ISFALSE	= 0	-1
ISFALSE	<> 0	0

PowerBASIC's NOT operator serves a double duty: it returns the one's-complement of an expression and "reverses" the value of a TRUE/FALSE (Boolean) expression. Usually, these two functions do not conflict, but since PowerBASIC accepts any non-zero value as TRUE, the following condition can arise:

```
test1 = 0           ' test1 is FALSE (zero)
IF NOT test1 THEN   ' TRUE (-1 is non-zero)
[statements]

test2 = 1           ' test2 is TRUE (1 is non-zero)
IF NOT test2 THEN   ' still TRUE (-2 is non-zero)
[statements]
```

In this case, NOT does not reverse the TRUE/FALSE value of test2. ISFALSE ensures that the test is performed exactly as you would expect:

test2 = 1 ' test2 is TRUE (non-zero)

```
IF ISFALSE test2 THEN ' ISFALSE detects test2 is
[statements]          ' TRUE so the IF test fails
```

This problem does not exist when you're testing for logical truth. PowerBASIC considers that an expression is TRUE in every case *except* when the expression is zero. However, ISTRUE converts all non-zero values to the "most true" value, -1, which provides the most consistent results with both boolean and arithmetic expressions.

Restrictions ISTRUE and ISFALSE operators evaluate the "whole" expression following the keyword, subject to their Operator Precedence level. For example, parentheses contained within the expression are regarded as an integral part of the expression, and do not act as delimiters for the ISTRUE and ISFALSE operators.

With this in mind, combining a logical test result into a further expression means that the expressions must be separated to ensure the correct evaluation.

Consider the following statement:

```
IF ISTRUE (x&) + y& THEN
```

PowerBASIC evaluates the entire expression *(x&) + y&* and then calculates the logical truth from the overall result of that expression. That is, the parentheses around the first part of the expression do not stop ISTRUE from evaluating the whole expression. To demonstrate this, the statement can be rewritten to concisely demonstrate the scope of the logical evaluation:

```
IF ISTRUE (x& + 2) THEN
```

or it could be simplified even further:

```
IF ISTRUE x& + 2 THEN
```

If you wish to utilize the numeric result of the logical test in a further expression, parentheses must be added to separate the expressions correctly:

```
IF (ISTRUE x&) + 2 THEN
```

See also Arithmetic Operators, NOT, Short-circuit evaluation

ISWIN function

Keyword Template

Purpose

Syntax

Remarks

See also

Example

ISWIN function

Purpose Determine whether a

/Dialog/Window currently exists

Syntax

```
DialogExists&  = ISWIN(hDlg&)
ControlExists& = ISWIN(hParentDlg&, Ident&)
```

Remarks The Window subsystem is checked to determine whether the specified Dialog or Control currently exists. This function may be used for a wide range of purposes, but it's particularly valuable when you want to be sure that a CONTROL was created successfully with the

statement.

If you use a single parameter, it must specify the handle of a Window, Dialog, or Control you are checking. If you use two parameters, you would specify the handle of the parent and the identifier of the Control you are checking.

If the target of the function currently exists, TRUE (-1) is returned. If it does not exist, the return value is FALSE (0).

See also , CONTROL HANDLE, DIALOG NEW

ITERATE statement

ITERATE statement

Purpose Start an immediate iteration of a

structure.

Syntax

```
ITERATE [DO | LOOP | FOR]
```

Remarks ITERATE is just like using a GOTO to the line immediately before the NEXT statement (of a FOR...NEXT loop), the LOOP statement (of a DO...LOOP loop), or the WEND statement (of a WHILE..WEND loop). For example, the following code fragments are equivalent:

```
FOR ix = 1 TO 100
  [statements]
```

```
  ITERATE FOR
  [statements]
NEXT

FOR ix = 1 TO 100
  [statements]
  GOTO iterateForLoop
  [statements]
iterateForLoop:
NEXT
```

If you do not specify DO, LOOP, or FOR, ITERATE will iterate the most recently executed structure. For example:

```
FOR ix = 1 TO 10
  DO UNTIL x > 10
    [statements]
    ITERATE  ' will iterate the DO LOOP
    [statements]
  LOOP
NEXT
ITERATE DO and ITERATE LOOP are interchangeable.
```

Use this statement...	To iterate this kind of loop
ITERATE FOR	FOR/NEXT
ITERATE DO, ITERATE LOOP	DO/LOOP, WHILE/WEND

See also DO/LOOP, EXIT, FOR EACH/NEXT, FOR/NEXT, WHILE/WEND

JOIN$ function

JOIN$ function

Purpose Return a

consisting of all of the strings in an array, each separated by a delimiter.

Syntax ***A$* = JOIN$(*array()*, {*delim$* | BINARY})**

Remarks JOIN$ requires a delimiter string *delim$* which may be any length.

If the delimiter expression is a null (zero-length) string, no separators are inserted between the string sections. If the delimiter expression is the 3-byte value of "," (which may be expressed in your source code as the string literal """,""") , a leading and trailing double-quote is added to each string section. This ensures that the returned string contains standard, comma-delimited quoted fields that can be easily parsed.

The array specified by *array()* may be any data type.

BINARY If the array consists of fixed size elements (

, Nul-Terminated Strings, etc.), the returned string consists of an exact memory image of the array data in internal format. If the array contains variable length data (Dynamic string, Field string), it is stored in PowerBASIC and/or Visual Basic packed string format: If a string is shorter than 65535 bytes, it starts with a 2-byte length WORD followed by the string data. Otherwise, it will start with a 2-byte value of 65535, followed by a DWORD indicating the string length, then finally the string data itself.

The JOIN$ function is the natural complement to the PARSE statement.

See also BUILD$, PARSE, PARSE$, PARSECOUNT

Example

```
FUNCTION PBMAIN
  DIM a$(2), s1$, s2$
  a$(0) = "Hello"
```

```
  a$(1) = "Power"
  a$(2) = "BASIC"
  s1$ = JOIN$(a$(),""",""")
  s2$ = JOIN$(a$(),$SPC)
END FUNCTION
```

Result

```
s1$ contains:  "Hello","Power","BASIC"
s2$ contains:  Hello Power BASIC
```

KILL statement

KILL statement

Purpose Delete a disk file.

Syntax **KILL *filespec***

Remarks *filespec* is a string expression specifying the file or files to be deleted, and can include a path name and/or "wildcard" characters. *filespec* may be either a Short File Name (SFN) or a Long File Name (LFN). For example:

```
KILL "TEST.DOC"
KILL "C:\MY APPLICATION DATA\INCOME.?87"
MyFile$ = "*.BAS"
KILL MyFile$     ' Potentially dangerous!
```

If *filespec* does not exist, Error 53 ("File not found") is generated. If *filespec* is read only, Error 70 ("Permission denied") occurs. You should not attempt to KILL an open file.

Files with the HIDDEN or SYSTEM attribute can not be deleted with KILL. An attempt to do so is ignored, with no error generated.

KILL is analogous to the DOS "DEL" and "ERASE" commands. KILL cannot delete a directory - use RMDIR instead, after first deleting all the files in the directory.

See also FILEATTR, FILECOPY, FILENAME$, GETATTR, NAME, RMDIR, SETATTR, SETEOF

LBOUND function

LBOUND function

Purpose Return the smallest possible subscript (boundary) for an array's specified dimension.

Syntax

```
y& = LBOUND(array [(dimension)])
y& = LBOUND(array, dimension)
```

Remarks LBOUND can be used in combination with UBOUND to determine the size of an array. LBOUND of an undimensioned array returns zero. The LBOUND function has the following parts:

array Name of the array of interest.

dimension An

indicating which dimension's lower bound is returned. If not specified, the first dimension is assumed.

Restrictions LBOUND cannot be used on arrays within User-Defined Types.

See also ARRAYATTR, DIM, REDIM, UBOUND

Example

```
' Dimension an array with lower and upper bounds
DIM MyArray%(1900 TO 2000,5 TO 10)
' get the values of the array
l1 = LBOUND(MyArray%)
u2 = UBOUND(MyArray%)
l2 = LBOUND(MyArray%(2))
```

```
u2 = UBOUND(MyArray%, 2)
```

LCASE$ function

LCASE$ function

Purpose Return a lowercase version of a

argument.

Syntax `s$ = LCASE$(string_expression [,ANSI | OEM])`

Remarks LCASE$ returns a string equivalent to *string_expression*, except that uppercase letters in *string_expression* are converted to lowercase. The optional ANSI or OEM parameter specifies whether the conversion is made using the ANSI charset for the system, or the original IBM OEM charset. If no charset is specified, PowerBASIC for Windows uses the system ANSI charset, while PB/CC uses the IBM OEM charset. Only "International" characters in the range of CHR$(128) to CHR$(255) are affected by this parameter.

The OEM charset is based upon the original IBM OEM charset to ensure compatibility with programs written for all previous versions of the PowerBASIC compiler.

See also MCASE$, UCASE$

Example
```
x$ = LCASE$("Cats aren't ALWAYS good.")
```

Result
```
cats aren't always good.
```

LEFT$ function

LEFT$ function

Purpose Return the left-most *n* characters of a

.

Syntax `s$ = LEFT$(string_expression, n&)`

Remarks *n&* is a Long-integer expression and specifies the number of characters in *string_expression* to be returned.

LEFT$ returns a string consisting of the left most *n&* characters of its string argument. If *n&* is greater than or equal to the length of *string_expression*, all of *string_expression* is returned. If *n&* is zero, LEFT$ returns an empty string. If the length value parameter is negative, it is interpreted as LEN(*string_expression*)-ABS(*n&*). For example, LEFT$("1234567890",-2) returns "12345678".

See also EXTRACT$, INSTR, LTRIM$, MID$, RIGHT$, RTRIM$, SPLIT, TALLY, TRIM$, VERIFY

Example
```
' Demonstrate LEFT$ and RIGHT$ functions
DIM TestString$, x$, y$, n AS LONG
TestString$ = "ABCDEFGHIJKLMNOP"
FOR n = 1 TO 14 STEP 2
  x$ = LEFT$(TestString$,n)
  y$ = RIGHT$(TestString$,n)
NEXT n
```

LEN function

LEN function

Purpose Return the logical length of a variable, User-Defined Type, or Union.

Syntax `y& = LEN(target)`

Remarks If *target* is a variable or a string expression, LEN returns a value from 0 to the current string length, representing the number of characters in *target*. If *target* is a fixed-length string, the length of the fixed buffer is returned. If *target* is an nul-terminated string, the length of the data stored in the nul-terminated string is returned, not the maximum size of the nul-terminated string. Use SIZEOF to determine the maximum size of an nul-terminated string.

When used with pointers, LEN returns a value of 4, since a pointer is always stored as a DWORD. You can use LEN with the target of a pointer to return the size of target. If the target is a dynamic string, you will receive the length of the string, not the length of the handle.

target can also be any other variable type, including and User-Defined Types (defined with TYPE/END TYPE). In that case, PowerBASIC will return the number of bytes needed to store a variable of that type.

When measuring the size of a padded (aligned) UDT structure with the LEN (or SIZEOF) statement, the measured length includes any padding that was added to the structure. For example, the following UDT structure:

```
TYPE LengthTestType DWORD
  a AS INTEGER
END TYPE
' code here
DIM abc AS LengthTestType
x& = LEN(abc)
```

Returns a length of 4 bytes in *x&*, since the UDT was padded with 2 additional bytes to enforce DWORD alignment. Note that the LEN of individual UDT members returns the true size of the member without regard to padding or alignment. In the previous example, LEN(abc.a) returns 2.

See also CHRBYTES, SIZEOF

Example

```
DIM p AS BYTE POINTER
ByteLen = LEN(p)  ' size of a pointer = 4 bytes
ByteLen = LEN(@p) ' size of byte (target) = 1 byte
```

LET statement

Keyword Template

Purpose

Syntax

Remarks

See also

Example

LET statement

Purpose Assign a value to a variable.

Syntax

```
[LET] variable  = expression
[LET] variable += expression
[LET] variable -= expression
[LET] variable *= expression
```

```
[LET] variable /= expression
[LET] variable \= expression
[LET] variable &= expression
[LET] variable AND= expression
[LET] variable OR= expression
[LET] variable EQV= expression
[LET] variable IMP= expression
[LET] variable MOD= expression
[LET] variable XOR= expression
```

Remarks

Simple assignment

variable is a

or variable, and expression is of a suitable type (that is, a string expression for string variables and numeric expression for numeric variables).

The word LET is optional in assignment statements. It is allowed to provide compatibility BASIC source files written for early versions of BASIC. In practice, the word LET is very rarely used.

To allow easy conversion, PowerBASIC allows a User-Defined Type in a string expression. The User-Defined Type is simply copied, byte for byte, into the expression. However, to assign a string back to a User-Defined Type, you should use the TYPE SET statement.

```
DIM abc as MyType
MyString$ = abc
```

Please refer to the following sections of the LET statement for special information regarding assignment using Object variables, Variant variables, and User-Defined Type variables.

Compound assignment

A compound assignment statement combines a binary arithmetic operator, a binary

, or a binary string operator (concatenation) as an integral part of the assignment. This offers the programmer a "shortcut" in your source code, and can even result in more efficient code generation. That's because the target variable is evaluated only once, even if an array or pointer calculation could have a side effect which changes it.

Compound assignments are available for the standard arithmetic operations of add, subtract, multiply, divide, int-divide, and modulo (+ - * / \ MOD), the bitwise operations (AND, OR, XOR, EQV, IMP), and the concatenation operators (+ &). Each are represented by one of the following tokens:

`+=`	`AND=`
`-=`	`OR=`
`/=`	`EQV=`
`\=`	`IMP=`
`&=`	`MOD=`
`*=`	`XOR=`

Each of the following pairs of code are functionally identical:

`x = x + 1`	`x += 1`
`x = x / y`	`x /= y`
`x = x XOR 3`	`x XOR= 3`
`x(7) = x(7) AND 5`	`x(7) AND= 5`
`x$ = x$ + y$`	`x$ += y$`

See also BUILD$, JOIN$, LET (with Objects), LET (with Variants), LET (with Types), TYPE SET

Example

```
MyString$ = "This is a test."
LET TempStr$ = MyString$
LET MyVarr -= YourVar
```

LET statement (with Objects)

Keyword Template

Purpose

Syntax

Remarks

See also

Example

LET statement (with Objects)

Purpose Assign an object reference to an object variable.

Syntax `[LET] objvar = object expression`

Remarks The LET Statement, and its implied form (without using the word LET), may be used to assign an object reference to an object variable. After you declare an object variable as a particular interface, you must create an object and or assign an object reference to it before you can use the objects members (methods, properties, etc.).

If an object creation or assignment fails for any reason, the *objvar* is set to NOTHING. If this statement fails, no errors are generated, nor is an OBJRESULT set. You should test for success of the operation with ISOBJECT(*objvar*) before trying to use the object or execute its methods.

LET *objvar* = CLASS *ClassName$*

The term *ClassName* must be specified as a quoted string literal, which is the name of a class implemented within the program. Since the class is internal (the name is known at compile-time), you may not use a

variable or expression. Upon execution, a new object is created, and a reference to that object is assigned to the object variable *objvar*. The interface requested is determined by the original declaration of *objvar*. If InterfaceName is DISPATCH, you can reference it with the OBJECT statement -- otherwise, regular Method and Property references are used.

LET *objvar* = NEWCOM *PrgID$*
LET *objvar* = GETCOM *PrgID$*
LET *objvar* = ANYCOM *PrgID$*

This form of the LET statement is used to obtain an object reference external to the program using the COM facilities of Windows. If the requested object is in a DLL (in-process server), you will always use the NEWCOM option, as you're asking for a new object. If the request is successful, the object reference is assigned to the *objvar*.

If the requested object is in an EXE (out-of-process server), you may use any of the three options. If the director word NEWCOM is specified, a new instance of a COM application is created. With GETCOM, an interface will be opened on an existing, running application, which has been registered as the active automation object for its class. With ANYCOM, the compiler will first try to use an existing, running application if available, or a new instance if not.

The string expression *ProID$* evaluates to a ProgID name on an external COM server. If the InterfaceName is DISPATCH, you can reference it with the OBJECT statement -- otherwise, regular Method and Property references are used instead.

LET *objvar* = NEWCOM CLSID *ClassID$*
LET *objvar* = GETCOM CLSID *ClassID$*
LET *objvar* = ANYCOM CLSID *ClassID$*

This form also obtains a COM object, just as the examples in the above section. There is always a one-to-one relationship between a ProgID and a CLSID (Class ID). An object can be identified by either of these tokens, as long as they are both available. In some instances, you may encounter an object which has no ProgID published. You can substitute the clause "CLSID *ClassID$*" for the *PrgID$*. It works exactly as the usual form above, except that it describes the requested object by its 16-byte GUID which is the CLSID (Class ID) of the object.

LET *objvar* = NEWCOM CLSID *ClassID$* LIB *DLLPath$*

PowerBASIC offers the unique ability to create and reference COM objects without any reference to the registry at all. As long as you know the CLSID (Class ID) and the file path/name of the DLL to be accessed, you can do so with no registry access at all. You don't need a special type of COM server. This technique can be used with any server, whether created by PowerBASIC or another compiler. By using this method of object creation, there is simply no need for the server to be registered at all. That allows you to keep local copies of the COM servers you use, with no chance they will be altered or replaced by another application. You use the above form, where the clause "CLSID *ClassID$*" identifies the 16-byte Class ID, and the clause "LIB *DllPath$*" identifies the file path and file name of the COM Server. Once you've obtained the COM object reference in *objvar*, it is used exactly as you would with a traditional object.

LET *objvar1* = *objvar2*

If both object variables have been declared as the same object type (the same interface name), the source variable (*objvar2*) is copied to the destination variable (*objvar1*), and the reference count of the object is incremented. If the object variables are of different object types, a new interface (of the type implied by *objvar1*) is opened on *objvar2*, and a reference to it is assigned to *objvar1*.

LET *objvar* = *objmethod*(*params*)

It is assumed that the METHOD or GET PROPERTY specified by *objmethod* returns an object of the type of *objvar*. The *objmethod* is evaluated, and the object reference which it returns is assigned to *objvar*.

LET *objvar* = ME

This form may only be used within a METHOD or PROPERTY. A new interface (of the type implied by *objvar*) is opened on the current object, and a reference to it is assigned to *objvar*.

LET *objvar* = NOTHING

This destroys an object variable, discontinuing its association with a specific object. This in turn releases all system and memory resources associated with the object when no more object variables refer to it.

LET *objvar* = *vrnt*

Attempts to open an interface of the specified class for *objvar* on the object of *vrnt*, and assigns a reference to *objvar*. It assumes that *vrnt* contains a reference to an object of type %VT_UNKNOWN or %VT_DISPATCH. If the desired interface can not be opened, the object variable *objvar* is set to NOTHING.

LET *vrnt* = *objvar*

This may be used to assign an object reference from an object variable to a variant variable. It attempts to open an IDispatch interface, else an IUnknown interface on the object of *objvar*, and assigns that reference to *vrnt*. Variant variables can not contain references to custom interfaces, only IDispatch or IUnknown. If the assignment is successful, VARIANTVT(*vrnt*) will return either %VT_UNKNOWN or %VT_DISPATCH. If it is unsuccessful, *vrnt* is set to %VT_EMPTY.

Previous versions of PowerBASIC Compilers used the SET statement for creation of objects. LET now includes all the functionality of the old SET statement, so you should plan to remove all SET statements as soon as possible. This involves nothing more than changing every SET to LET, or simply deleting every SET.

See also LET, LET (with Variants), LET (with Types), INTERFACE (Direct), INTERFACE (IDBind), ISINTERFACE,ISNOTHING, ISOBJECT, Just what is COM?, ME, OBJECT, What is an object, anyway?

LET statement (with Types)

Keyword Template

Purpose

Syntax

Remarks

See also

Example

LET statement (with Types) IMPROVED

Purpose Assign data to a user-defined type variable.

Syntax

```
[LET] TypeVar = TypeVar
[LET] TypeVar = VARIANT$(VrntVar)
```

Remarks *Typevar* is a user-defined type variable. In order to perform direct assignment of data from one user-defined type variable to another, they must be dimensioned to the same type. To assign data between two different types, you should use the TYPE SET statement instead.

The word LET is optional in assignment statements. It is allowed to provide compatibility BASIC source files written for early versions of BASIC. In practice, the word LET is very rarely used.

When User-Defined Type data is stored in a variant variable, it may be extracted as in the second syntax example. The Variant$() function understands that UDT data is stored as a byte string.

To allow easy conversion, PowerBASIC allows a User-Defined Type in a string expression. The User-Defined Type is simply copied, byte for byte, into the expression. To assign a string back to a User-Defined Type, you may also use the TYPE SET statement. Generally speaking, if a UDT is used in a WIDE string expression (Unicode), it will give unpredictable results from the character conversions.

```
DIM abc as MyType
MyString$ = abc
```

See also LET, LET (with Objects), LET (with Variants), TYPE SET, VARIANT$

Example

```
MyString$ = "This is a test."
LET TempStr$ = MyString$
```

LET statement (with Variants)

Keyword Template

Purpose

Syntax

Remarks

See also

Example

LET statement (with Variants) IMPROVED

Purpose Assign a value or an object reference to a variant variable.

Syntax

```
[LET] VariantVar = variant expression
[LET] VariantVar = TypeVar AS STRING
```

Remarks Although notoriously lacking in efficiency, Variant variables are commonly used as COM Object parameters due to their flexibility. They also prove valuable in a situation where a procedure must run properly with parameters of multiple data types (a Collection would be a good example). You can think of a Variant as a kind of container, which can hold a variable of most any data type,

, , object, or even a UDT or an entire array. This simplifies the process of calling procedures in a COM Object Server, as there is little need to worry about the myriad of possible data types for each parameter.

This flexibility comes at a great price in performance, so PowerBASIC limits their use to data storage and parameters only. You may assign a numeric value, a string value, a UDT, an object, or even an entire array to a Variant with the LET statement, or its implied equivalent. In the same way, you may assign one Variant value to another Variant variable, or even assign an array contained in a Variant to a compatible PowerBASIC array, or the reverse.

You may extract a scalar value from a Variant with VARIANT# (for numeric values), VARIANT$ (for ANSI byte strings or user-defined types), or VARIANT$$ (for wide Unicode strings). When you assign string data to a variant variable, ANSI strings are automatically converted to wide Unicode characters, as this is the accepted standard for variants. However, when you assign UDT data to a variant variable, it is stored as a dynamic string of bytes. When you retrieve that UDT data (with Variant$), PowerBASIC understands the content and handles it accurately. However, other programming languages may not, so the use of this technique should be limited to PowerBASIC applications.

LET *VrntVar*= *vrntvar*

This form duplicates the contents of one variant variable, assigning it to a second variant variable.

LET *VrntVar*= *expression* [AS *vartype*]

The numeric or string expression is evaluated, and the result is stored in the variant variable. PowerBASIC will choose an appropriate numeric or string data type to use. However, you can specify a preferred format by adding an optional AS vartype clause. This can be BYTE, WORD, DWORD, INTEGER, LONG, QUAD, SINGLE, DOUBLE, CURRENCY, or WSTRING. Strings in a variant are always stored in wide Unicode, regardless of whether you add AS WSTRING or not. PowerBASIC handles the conversion automatically, if it is needed.

In prior versions of PowerBASIC, the term AS STRING was interpreted to mean AS WSTRING for wide Unicode. However, with the new support for Unicode data types, this can no longer be allowed. All references to AS STRING with variants must be changed to AS WSTRING.

LET *VrntVar* = *TypeVar* AS STRING

The data contained in the User-Defined Type variable (UDT) is stored in the variant variable. It is stored internally as a dynamic string of bytes (vt_bstr). When you retrieve that UDT data (with Variant$), PowerBASIC understands the content and handles it accurately. However, other programming languages may not understand this technique, so it should generally be limited to PowerBASIC applications.

In prior versions of PowerBASIC, the AS STRING clause was not a requirement, as it is currently. Although it represents a change, it was a necessary restriction to confirm that the conversion to string is your intention.

LET *VrntVar* = EMPTY

The variant variable is set to %VT_EMPTY, which means it contains no value of any kind.

LET *VrntVar* = ERROR *numr*

This form assigns a specific COM error number, which is usually a COM specific error, such as %E_NOINTERFACE, etc.

LET *VrntVar* = *array()*

An entire PowerBASIC array is assigned to a variant variable. In the case of a string array, PowerBASIC automatically handles Unicode conversions needed for the COM specification. Array assignment is limited to the following data types: BYTE, WORD, DWORD, INTEGER, LONG, QUAD, SINGLE, DOUBLE, CURRENCY, or STRING, as Windows does not support all PowerBASIC data forms.

LET *array()* = *vrntvar*

An entire array is assigned from a variant variable to a PowerBASIC array. In the case of a string array, PowerBASIC automatically handles Unicode conversions. You can not assign an array with more than eight dimensions to a PowerBASIC array.

LET *VrntVar* = BYREF *variable*

This form is used to allow a variant to contain a typed pointer to a specific variable. Any changes to the variant will cause the variable to be changed, as it is the target of the pointer. The variable may be of any data type which is supported by variants and COM objects: Byte, Word, Dword, Integer, Long, Quad, Single, Double, Currency, Variant, String, and WString. If you attempt to use an unsupported variable type (like Extended, Bit, STRINGZ, etc.), PowerBASIC will generate an error 482 (Data Type Mismatch). Further, you may not use a register variable (automatic or explicit), or an error 491 (Invalid Register Variable) will be generated. Note that strings used with COM objects are expected to be in Unicode format, rather than ANSI. The ACODE$ and UCODE$ functions may be used to convert the strings as necessary. You should exercise caution with a BYREF ANSI string, as it may not be recognized accurately by other code which expects only Unicode strings.

LET *objvar* = *vrnt*

Attempts to open an interface of the specified class for *objvar* on the object of *vrnt*, and assigns a reference to *objvar*. It assumes that *vrnt* contains a reference to an object of type %VT_UNKNOWN or %VT_DISPATCH. If the desired interface can not be opened, the object variable *objvar* is set to NOTHING. You can test for success/failure with the ISOBJECT(*objvar*) function.

LET *vrnt* = *objvar*

This may be used to assign an object reference from an object variable to a variant variable. It attempts to open an IDispatch interface, else an IUnknown interface on the object of *objvar*, and assigns that reference to *vrnt*. Variant variables can not contain references to custom interfaces, only IDispatch or IUnknown. If the assignment is successful, VARIANTVT(*vrnt*) will return either %VT_UNKNOWN or %VT_DISPATCH. If it is unsuccessful, *vrnt* is set to %VT_EMPTY.

LIBMAIN function

LIBMAIN function

Purpose LIBMAIN (or its synonym DLLMAIN) is an optional user-defined function called by Windows each time a DLL is loaded into, and unloaded from, memory. The PBLIBMAIN function performs a similar task to LIBMAIN, but takes no parameters.

Syntax

```
FUNCTION { LIBMAIN | DLLMAIN } ( _
  BYVAL hInstance AS DWORD, _
  BYVAL lReason AS LONG, _
  BYVAL lReserved AS LONG ) AS LONG
```

In 32-bit Windows, LIBMAIN is called by Windows each time a DLL is loaded or unloaded by an application or process, and (usually) when a thread is started and stopped. Your code should never call LIBMAIN.

Remarks The LIBMAIN / DLLMAIN function provides the following parameters:

hInstance The unique instance handle of the DLL. This handle is used by the calling application to identify the DLL. The instance handle value is commonly used to load resources embedded within the DLL, and to obtain the actual file name of the DLL (via the GetModuleFilename API function). In these cases, it is common to copy the *hInstance* value to a global variable, allowing the instance handle value to be utilized elsewhere in the DLL.

lReason This flag indicates why the DLL entry-point is being called. It can be one of the following values (as defined in WIN32API.INC):

%DLL_PROCESS_ATTACH	Indicates that the DLL is being loaded by a process (another DLL or EXE is loading the DLL). DLLs can use this opportunity to initialize any instance or global data, such as arrays. *lReserved* is zero if the DLL is being loaded explicitly (run-time linking) using LoadLibrary(), or non-zero if the DLL is being loaded implicitly (load-time linking) during process initialization.
%DLL_PROCESS_DETACH	Indicates that the DLL is being cleanly unloaded or detached from the calling application. DLLs can take this opportunity to clean up all resources for all threads attached and known to the DLL. This is functionally equivalent to the WEP function in 16-bit DLLs. *lReserved* is zero if LIBMAIN was executed via the FreeLibrary API and the DLLs reference count reached zero (no further instances of the DLL are loaded), or non-zero if LIBMAIN is executed during process termination. A %DLL_PROCESS_DETACH does not generate %DLL_THREAD_DETACH for active threads.
%DLL_THREAD_ATTACH	Indicates that the DLL is being loaded by a new thread in the calling application. DLLs can use this opportunity

	to initialize any Thread Local Storage (TLS). This execution occurs in the context of the new thread.
%DLL_THREAD_DETACH	Indicates that the thread is exiting cleanly. If the DLL has allocated any thread-specific storage (Thread Local Storage or TLS), it should be released. This may occur even if there was no matching %DLL_THREAD_ATTACH call. A %DLL_PROCESS_DETACH does not generate %DLL_THREAD_DETACH for active threads.

lReserved The *lReserved* parameter specifies further aspects of the DLL initialization and cleanup. If *lReason* is %DLL_PROCESS_ATTACH, *lReserved* is zero (0) for explicit (dynamic) loads and non-zero for implicit loads. If *lReason* is %DLL_PROCESS_DETACH, *lReserved* is zero if LIBMAIN has been called by using the FreeLibrary API call, and non-zero if LIBMAIN has been called during process termination.

Return value If LIBMAIN is called with %DLL_PROCESS_ATTACH, your LIBMAIN function should return a zero (0) if any part of your initialization process fails, or a one (1) if no errors were encountered. If a zero is returned, Windows will abort and unload the DLL from memory. When LIBMAIN is called with any other value than %DLL_PROCESS_ATTACH, the return value is ignored.

Restrictions Note that Windows does not guarantee that LIBMAIN will be called in a "balanced" manner. For example, a %DLL_PROCESS_ATTACH is not followed by a %DLL_THREAD_ATTACH for the primary thread. In some conditions, %DLL_THREAD_DETACH may not occur at all. Further discussion on these Windows traits are beyond the scope of this documentation; however, an excellent source of information can be found in "Win32 Programming", Rector/Newcomer, ISBN 0-201-63492-9.

At the point where a DLL is loaded into memory during process startup, Windows only guarantees that the KERNEL32.DLL system library will be loaded in memory. On this basis, API calls made from within LIBMAIN must be restricted to the range of API functions present in KERNEL32.DLL, with the exception of the LoadLibrary, LoadLibraryEx, and FreeLibrary API functions.

In addition, code within LIBMAIN must not call API functions in any other DLL (for example, USER32.DLL, SHELL32.DLL, ADVAPU32.DLL, GDI32.DLL, etc), because some API functions in those DLLs may attempt to load other libraries via LoadLibrary, etc. For example, never call the MessageBox API function from within LIBMAIN, nor use the related MSGBOX function or MSGBOX statement.

Failure to observe these restrictions will result in Access Violation or General Protection Faults (GPFs), typically caused by the execution of code in DLLs that has yet to be initialized.

See also DLLMAIN, PBLIBMAIN, PBMAIN, THREAD CREATE, WINMAIN

Example

```
#DIM ALL
#COMPILE DLL "LIBTEST.DLL"
#INCLUDE "WIN32API.INC"

GLOBAL gNumOfTimes AS DWORD

FUNCTION LIBMAIN(BYVAL hInstance AS DWORD, _
  BYVAL lReason AS LONG, _
  BYVAL lReserved AS LONG) AS LONG

  INCR gNumOfTimes

  SELECT CASE AS LONG lReason

    CASE %DLL_PROCESS_ATTACH
      ' This DLL has been mapped into the memory context of
      ' the calling program, and can be initialized as required.
      ' Here we return a non-zero LIBMAIN result to indicate success.
```

```
        LIBMAIN = 1
        EXIT FUNCTION

      CASE %DLL_PROCESS_DETACH
        ' This DLL is about to be unloaded
        EXIT FUNCTION

      CASE %DLL_THREAD_ATTACH
        ' A [New] thread is starting (see THREADID)
        EXIT FUNCTION

      CASE %DLL_THREAD_DETACH
        ' This thread is closing (see THREADID)
        EXIT FUNCTION

    END SELECT

    ' Theoretically execution should never get to this point.
    ' However, if the DLL is being implicitly linked then return
    ' Zero (0) and the process (program) will fail to start
    ' running. For Explicit linking, returning Zero (0) will
    ' simply cause the LoadLibrary/LoadLibraryEx API call to fail.
    LIBMAIN = 0 ' Indicate failure to initialize the DLL!
  END FUNCTION

  SUB TestIt ALIAS "TestIt" () EXPORT
    MSGBOX "TestIt" + $CRLF + _"gNumOfTimes =" + STR$(gNumOfTimes)
  END SUB
```

LINE INPUT# statement

LINE INPUT# statement

Purpose
Read line(s) from a sequential file into a variable or string array, ignoring delimiters.

Syntax
LINE INPUT #*filenum&*, *string_variable*
LINE INPUT #*filenum&*, *Arr$()* [RECORDS *rcds*] [TO *count*]

Remarks
filenum& is the file number, or variable containing a file number, given when the file was opened. *string_variable* is the string variable to be loaded with the data read from the file.

string_variable may be a fixed-length, nul-terminated, or dynamic string. For fixed-length and nul-terminated strings, data that is longer than the string is truncated to fit into the string. Dynamic strings receive the data without truncation. *string_variable* may not be a UDT variable, although fixed-length and nul-terminated UDT member variables are supported.

LINE INPUT# is intended for use with text files composed of lines terminated by CR/LF ($CRLF or CHR$(13,10)) sequences. It reads a line from the file and returns it, minus the CR/LF delimiter. Commas, quotation marks and other characters have no special meaning for LINE INPUT#, and are treated like any other text.

If the file consists of comma-delimited data items, INPUT# is likely to be more suitable then LINE INPUT#.

The second syntax definition of LINE INPUT# reads a file opened for INPUT, assigning full lines of text to each element of the array.

It is assumed the data is standard text, delimited by a CR/LF ($CRLF) or EOF (1A hex or $EOF). LINE INPUT# attempts to read the number of lines specified in the RECORDS *rcds* option, or the number of elements in the array, whichever is smaller.

The actual number of lines read is assigned to the variable specified in the optional TO *count* clause. FILESCAN is useful in conjunction, to determine the dimensioned size of the string array. EOF is set just as with single Line Input.

See also EOF, FILESCAN, INPUT#, PRINT#

Example

```
SUB MakeFile
  ' Open a sequential file for output. Use PRINT#
  ' to write different data types to the file.
  OPEN "LINEINP#.DTA" FOR OUTPUT AS #1

  ' Define some variables.
  sVar$ = "There's trouble in River City, by George."
  iVar% = 1000
  fpVar! = 30000.12

  ' Write a line of text to the file.
  PRINT# 1, sVar$; iVar%; fpVar!
  CLOSE #1      'close the file
END SUB 'end procedure MakeFile

SUB ReadFile
  'Open a sequential file for input, then use
  'LINE INPUT # to read lines of different
  'data types from the file.

  OPEN "LINEINP#.DTA" FOR INPUT AS #1
  StringVar$ = ""

  'Input an entire line regardless of length or
  'delimiters.
  LINE INPUT #1, StringVar$
  CLOSE #1      'close the file
END SUB 'end procedure ReadFile
```

LISTBOX ADD statement

Keyword Template

Purpose

Syntax

Remarks

Example

LISTBOX statement IMPROVED

Purpose Manipulate a LISTBOX control in order to set/retrieve data.

Syntax

```
LISTBOX ADD hDlg, id&, StrExpr [TO datav&]
LISTBOX DELETE hDlg, id&, item&
LISTBOX FIND hDlg, id&, item&, StrExpr TO datav&
LISTBOX FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTBOX GET COUNT hDlg, id& TO datav&
LISTBOX GET SELCOUNT hDlg, id& TO datav&
LISTBOX GET SELECT hDlg, id& [,item&] TO datav&
LISTBOX GET STATE hDlg, id&, item& TO datav&
```

```
LISTBOX GET TEXT hDlg, id& [,item&] TO txtv$
LISTBOX GET USER hDlg, id&, item& TO datav&
LISTBOX INSERT hDlg, id&, item&, StrExpr [TO datav&]
LISTBOX RESET hDlg, id&
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item& Position of data in the LISTBOX. First string=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg*, *id&*, *StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg*, *id&*, *item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1

(1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg, id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg, id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg, id&* [*,item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg, id&, item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg, id&* [*,item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg, id&, item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg, id&, item&, StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg, id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg, id&, item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg, id&, item&, StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg, id&, item&, NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg, id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions

Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

LISTBOX RESET hDlg, id&
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item& Position of data in the LISTBOX. First string=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg, id&, StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg, id&, item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire

LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg, id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg, id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg, id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg, id&, item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg, id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg, id&, item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg*, *id&*, *item&*, *StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg*, *id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg*, *id&*, *item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg*, *id&*, *item&*, *StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg*, *id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

Example

LISTBOX statement IMPROVED

Purpose Manipulate a LISTBOX control in order to set/retrieve data.

Syntax

```
LISTBOX ADD hDlg, id&, StrExpr [TO datav&]
LISTBOX DELETE hDlg, id&, item&
LISTBOX FIND hDlg, id&, item&, StrExpr TO datav&
LISTBOX FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTBOX GET COUNT hDlg, id& TO datav&
LISTBOX GET SELCOUNT hDlg, id& TO datav&
LISTBOX GET SELECT hDlg, id& [,item&] TO datav&
LISTBOX GET STATE hDlg, id&, item& TO datav&
LISTBOX GET TEXT hDlg, id& [,item&] TO txtv$
LISTBOX GET USER hDlg, id&, item& TO datav&
LISTBOX INSERT hDlg, id&, item&, StrExpr [TO datav&]
LISTBOX RESET hDlg, id&
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item& Position of data in the LISTBOX. First string=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg, id&, StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg, id&, item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg*, *id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg*, *id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg*, *id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg*, *id&*, *item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg*, *id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg, id&, item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg*, *id&*, *item&*, *StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg, id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg*, *id&*, *item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg*, *id&*, *item&*, *StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg*, *id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

LISTBOX GET USER hDlg, id&, item& TO datav&
LISTBOX INSERT hDlg, id&, item&, StrExpr [TO datav&]
LISTBOX RESET hDlg, id&
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item& Position of data in the LISTBOX. First string=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg*, *id&*, *StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg*, *id&*, *item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg*, *id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg*, *id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg*, *id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg*, *id&*, *item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg*, *id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*.

If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg*, *id&*, *item&*, *StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg*, *id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg*, *id&*, *item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg*, *id&*, *item&*, *StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg*, *id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item& Position of data in the LISTBOX. First string=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg*, *id&*, *StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg*, *id&*, *item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg*, *id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg*, *id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg*, *id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg*, *id&*, *item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg, id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg, id&, item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg, id&, item&, StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg, id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg, id&, item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg, id&, item&, StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg, id&, item&, NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg, id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

Example

LISTBOX statement IMPROVED

Purpose Manipulate a LISTBOX control in order to set/retrieve data.

Syntax

```
LISTBOX ADD hDlg, id&, StrExpr [TO datav&]
LISTBOX DELETE hDlg, id&, item&
LISTBOX FIND hDlg, id&, item&, StrExpr TO datav&
LISTBOX FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTBOX GET COUNT hDlg, id& TO datav&
LISTBOX GET SELCOUNT hDlg, id& TO datav&
LISTBOX GET SELECT hDlg, id& [,item&] TO datav&
LISTBOX GET STATE hDlg, id&, item& TO datav&
LISTBOX GET TEXT hDlg, id& [,item&] TO txtv$
LISTBOX GET USER hDlg, id&, item& TO datav&
LISTBOX INSERT hDlg, id&, item&, StrExpr [TO datav&]
LISTBOX RESET hDlg, id&
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item& Position of data in the LISTBOX. First string=1, second=2...

NumExpr A

	expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks

In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg, id&, StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg, id&, item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg, id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg, id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg, id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg, id&, item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg, id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg, id&, item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg, id&, item&, StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg, id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg, id&, item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg, id&, item&, StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg, id&, item&, NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg, id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

Example

LISTBOX statement IMPROVED

Purpose Manipulate a LISTBOX control in order to set/retrieve data.

Syntax

```
LISTBOX ADD hDlg, id&, StrExpr [TO datav&]
LISTBOX DELETE hDlg, id&, item&
LISTBOX FIND hDlg, id&, item&, StrExpr TO datav&
LISTBOX FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTBOX GET COUNT hDlg, id& TO datav&
LISTBOX GET SELCOUNT hDlg, id& TO datav&
LISTBOX GET SELECT hDlg, id& [,item&] TO datav&
LISTBOX GET STATE hDlg, id&, item& TO datav&
LISTBOX GET TEXT hDlg, id& [,item&] TO txtv$
LISTBOX GET USER hDlg, id&, item& TO datav&
LISTBOX INSERT hDlg, id&, item&, StrExpr [TO datav&]
LISTBOX RESET hDlg, id&
```

```
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item& Position of data in the LISTBOX. First string=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg, id&, StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg, id&, item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg*, *id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg*, *id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg*, *id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg*, *id&*, *item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg*, *id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg*, *id&*, *item&*, *StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg*, *id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg, id&, item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg, id&, item&, StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg, id&, item&, NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg, id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

Example

LISTBOX statement IMPROVED

Purpose Manipulate a LISTBOX control in order to set/retrieve data.

Syntax

```
LISTBOX ADD hDlg, id&, StrExpr [TO datav&]
LISTBOX DELETE hDlg, id&, item&
LISTBOX FIND hDlg, id&, item&, StrExpr TO datav&
```

```
LISTBOX FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTBOX GET COUNT hDlg, id& TO datav&
LISTBOX GET SELCOUNT hDlg, id& TO datav&
LISTBOX GET SELECT hDlg, id& [,item&] TO datav&
LISTBOX GET STATE hDlg, id&, item& TO datav&
LISTBOX GET TEXT hDlg, id& [,item&] TO txtv$
LISTBOX GET USER hDlg, id&, item& TO datav&
LISTBOX INSERT hDlg, id&, item&, StrExpr [TO datav&]
LISTBOX RESET hDlg, id&
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item& Position of data in the LISTBOX. First string=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg*, *id&*, *StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg*, *id&*, *item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg*, *id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg*, *id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg*, *id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg*, *id&*, *item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg*, *id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg*, *id&*, *item&*, *StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg, id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg, id&, item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg, id&, item&, StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg, id&, item&, NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg, id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

LISTBOX GET SELCOUNT hDlg, id& TO datav&
LISTBOX GET SELECT hDlg, id& [,item&] TO datav&
LISTBOX GET STATE hDlg, id&, item& TO datav&
LISTBOX GET TEXT hDlg, id& [,item&] TO txtv$
LISTBOX GET USER hDlg, id&, item& TO datav&
LISTBOX INSERT hDlg, id&, item&, StrExpr [TO datav&]
LISTBOX RESET hDlg, id&
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item& Position of data in the LISTBOX. First string=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg, id&, StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg, id&, item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive.

Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg, id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg, id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg, id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg, id&, item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg, id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg, id&, item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg*, *id&*, *item&*, *StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg*, *id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg*, *id&*, *item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg*, *id&*, *item&*, *StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg*, *id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

Example

LISTBOX statement IMPROVED

Purpose Manipulate a LISTBOX control in order to set/retrieve data.

Syntax

```
LISTBOX ADD hDlg, id&, StrExpr [TO datav&]
LISTBOX DELETE hDlg, id&, item&
LISTBOX FIND hDlg, id&, item&, StrExpr TO datav&
LISTBOX FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTBOX GET COUNT hDlg, id& TO datav&
LISTBOX GET SELCOUNT hDlg, id& TO datav&
LISTBOX GET SELECT hDlg, id& [,item&] TO datav&
LISTBOX GET STATE hDlg, id&, item& TO datav&
LISTBOX GET TEXT hDlg, id& [,item&] TO txtv$
LISTBOX GET USER hDlg, id&, item& TO datav&
LISTBOX INSERT hDlg, id&, item&, StrExpr [TO datav&]
LISTBOX RESET hDlg, id&
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item& Position of data in the LISTBOX. First string=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg*, *id&*, *StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg*, *id&*, *item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg*, *id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg*, *id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg*, *id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg*, *id&*, *item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg*, *id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg, id&, item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg, id&, item&, StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg, id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg, id&, item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg, id&, item&, StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg, id&, item&, NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg, id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of

	Windows, the actual string data contained by the list box is limited only by available memory.

LISTBOX GET USER hDlg, id&, item& TO datav&
LISTBOX INSERT hDlg, id&, item&, StrExpr [TO datav&]
LISTBOX RESET hDlg, id&
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg	Handle of the dialog that owns the list box.
id&	The control identifier assigned with CONTROL ADD LISTBOX.
item&	Position of data in the LISTBOX. First string=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg*, *id&*, *StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg*, *id&*, *item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg*, *id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg*, *id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg*, *id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg*, *id&*, *item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg*, *id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg*, *id&*, *item&*, *StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg*, *id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg*, *id&*, *item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg*, *id&*, *item&*, *StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET

USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg*, *id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item& Position of data in the LISTBOX. First string=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg*, *id&*, *StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg*, *id&*, *item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg*, *id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg*, *id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg*, *id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg*, *id&*, *item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg*, *id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg*, *id&*, *item&*, *StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg*, *id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg*, *id&*, *item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg*, *id&*, *item&*, *StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg, id&, item&, NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg, id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

Example

LISTBOX statement IMPROVED

Purpose Manipulate a LISTBOX control in order to set/retrieve data.

Syntax

```
LISTBOX ADD hDlg, id&, StrExpr [TO datav&]
LISTBOX DELETE hDlg, id&, item&
LISTBOX FIND hDlg, id&, item&, StrExpr TO datav&
LISTBOX FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTBOX GET COUNT hDlg, id& TO datav&
LISTBOX GET SELCOUNT hDlg, id& TO datav&
LISTBOX GET SELECT hDlg, id& [,item&] TO datav&
LISTBOX GET STATE hDlg, id&, item& TO datav&
LISTBOX GET TEXT hDlg, id& [,item&] TO txtv$
LISTBOX GET USER hDlg, id&, item& TO datav&
LISTBOX INSERT hDlg, id&, item&, StrExpr [TO datav&]
LISTBOX RESET hDlg, id&
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item&	Position of data in the LISTBOX. First string=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks

In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg*, *id&*, *StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg*, *id&*, *item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg*, *id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg*, *id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg*, *id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg*, *id&*, *item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg*, *id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg*, *id&*, *item&*, *StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg*, *id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg*, *id&*, *item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg, id&, item&, StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg, id&, item&, NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg, id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

LISTBOX INSERT hDlg, id&, item&, StrExpr [TO datav&]
LISTBOX RESET hDlg, id&
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg	Handle of the dialog that owns the list box.
id&	The control identifier assigned with CONTROL ADD LISTBOX.
item&	Position of data in the LISTBOX. First string=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks

In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg*, *id&*, *StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg*, *id&*, *item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg*, *id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg*, *id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg*, *id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg*, *id&*, *item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg*, *id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg*, *id&*, *item&*, *StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg, id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg, id&, item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg, id&, item&, StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg, id&, item&, NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg, id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

LISTBOX GET SELCOUNT hDlg, id& TO datav&
LISTBOX GET SELECT hDlg, id& [,item&] TO datav&
LISTBOX GET STATE hDlg, id&, item& TO datav&
LISTBOX GET TEXT hDlg, id& [,item&] TO txtv$
LISTBOX GET USER hDlg, id&, item& TO datav&
LISTBOX INSERT hDlg, id&, item&, StrExpr [TO datav&]
LISTBOX RESET hDlg, id&
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item& Position of data in the LISTBOX. First string=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg, id&, StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg, id&, item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire

LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg*, *id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg*, *id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg*, *id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg*, *id&*, *item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg*, *id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg*, *id&*, *item&*, *StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg*, *id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg*, *id&*, *item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg*, *id&*, *item&*, *StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg*, *id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

Example

LISTBOX statement IMPROVED

Purpose Manipulate a LISTBOX control in order to set/retrieve data.

Syntax

```
LISTBOX ADD hDlg, id&, StrExpr [TO datav&]
LISTBOX DELETE hDlg, id&, item&
LISTBOX FIND hDlg, id&, item&, StrExpr TO datav&
LISTBOX FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTBOX GET COUNT hDlg, id& TO datav&
LISTBOX GET SELCOUNT hDlg, id& TO datav&
LISTBOX GET SELECT hDlg, id& [,item&] TO datav&
LISTBOX GET STATE hDlg, id&, item& TO datav&
LISTBOX GET TEXT hDlg, id& [,item&] TO txtv$
LISTBOX GET USER hDlg, id&, item& TO datav&
LISTBOX INSERT hDlg, id&, item&, StrExpr [TO datav&]
LISTBOX RESET hDlg, id&
LISTBOX SELECT hDlg, id&, item&
LISTBOX SET TEXT hDlg, id&, item&, StrExpr
LISTBOX SET USER hDlg, id&, item&, NumExpr
LISTBOX UNSELECT hDlg, id& [,item&]
```

hDlg Handle of the dialog that owns the list box.

id& The control identifier assigned with CONTROL ADD LISTBOX.

item& Position of data in the LISTBOX. First string=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks In each of the following samples and descriptions, the LISTBOX control which is the subject of the statement is identified by the handle of the dialog that owns the LISTBOX (*hDlg*), and the unique control identifier you gave it upon creation in CONTROL ADD LISTBOX.

The value *item&* refers to the position of the string data item in the LISTBOX, and is always indexed to one. The first string is position 1, the second is position 2, and so forth.

LISTBOX ADD *hDlg, id&, StrExpr* [TO *datav&*]

The string value specified by *StrExpr* is added to the LISTBOX control. If the LISTBOX has the %LBS_SORT style, the new string is inserted in alphanumeric order; otherwise it is added to the end of the existing list. If the optional TO clause is included, the index position of the added string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was added.

LISTBOX DELETE *hDlg, id&, item&*

The string at the position specified by *item&* is deleted from the LISTBOX. The parameter *item&* is indexed to one (1 for the first string, 2 for the second, and so on).

LISTBOX FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the LISTBOX are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTBOX. Searching does not wrap to the beginning of the list. The item number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTBOX starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTBOX GET COUNT *hDlg, id&* TO *datav&*

The number of items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELCOUNT *hDlg, id&* TO *datav&*

The number of selected items in the LISTBOX is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTBOX GET SELECT *hDlg, id&* [,*item&*] TO *datav&*

The LISTBOX is searched to find the first selected item. If the *item&* parameter is included, searching starts at that position to facilitate retrieving multiple selected items. If *item&* is omitted, the search starts at the first data item. The index number of the selected item is assigned to the variable designated by *datav&*. If no item is selected, the value zero (0) is assigned to it.

LISTBOX GET STATE *hDlg, id&, item&* TO *datav&*

A data item is checked to see if it is currently selected. The numeric value *item&* specifies which user value is to be checked, 1 for the first item, 2 for the second item, etc. If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTBOX GET TEXT *hDlg, id&* [,*item&*] TO *txtv$*

Text is retrieved from the LISTBOX and assigned to the string variable specified by *txtv$*. If the numeric expression *item&* is included, it determines which text string is returned, 1 for the first item, 2 for the second item, etc.

The parameter *item&* may be omitted, or contain the value zero (0). In the case of a single-selection listbox, the current selected text (if any) is retrieved and assigned to *txtv$*. With a multiple-selection listbox (%LBS_MULTIPLESEL or %LBS_EXTENDEDSEL style), the text of the first (base) selected item is assigned to *txtv$*. To retrieve additional selected text items from a multiple-selection listbox, use LISTBOX GET SELECT to retrieve selected item numbers. Then apply the item numbers with LISTBOX GET TEXT to retrieve the string data.

LISTBOX GET USER *hDlg, id&, item&* TO *datav&*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first item, 2 for the second item, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTBOX user values are assigned with the LISTBOX SET USER statement. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX INSERT *hDlg*, *id&*, *item&*, *StrExpr* [TO *datav&*]

The text for a new data item, specified by *StrExpr*, is inserted at the location given by *item&*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort all of the items, use LISTBOX ADD instead. If the optional TO clause is included, the index position of the inserted string is assigned to the variable represented by *datav&*. The index is one for the first string, two for the second, etc. If the index is less than one, an error occurred and no string was inserted.

LISTBOX RESET *hDlg, id&*

Delete all contents of the specified LISTBOX.

LISTBOX SELECT *hDlg*, *id&*, *item&*

The string data item specified by *item&* is chosen as selected text for the LISTBOX control, and the selected text is scrolled into a visible position. The value of *item&* = 1 for the first item, 2 for the second item, etc. If the value of *item&* = 0 with a multiple selection listbox, then all string data items are selected. LISTBOX SELECT may be used with both single and multiple selection listboxes.

LISTBOX SET TEXT *hDlg*, *id&*, *item&*, *StrExpr*

The text for the data item specified by *item&* is replaced with the new text in *StrExpr*. The value of *item&* = 1 for the first item, 2 for the second item, etc. The list of data items is not re-sorted, even if the LISTBOX was created with the style %LBS_SORT. If you wish to sort the items, use LISTBOX DELETE followed by LISTBOX ADD instead.

LISTBOX SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each item in a LISTBOX may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTBOX SET USER, and retrieved with LISTBOX GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTBOX user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTBOX UNSELECT *hDlg, id&* [,*item&*]

The string value specified by *item&* is set to an unselected state for the LISTBOX control. The value of *item&* = 1 for the first item, 2 for the second item, etc. If *item&* is missing, or has the value zero, all items are set to an unselected state. LISTBOX UNSELECT may be used with both single and multiple selection listboxes.

Restrictions Under Windows 95/98/ME, a list box is limited to 32,767 items. In all versions of Windows, the actual string data contained by the list box is limited only by available memory.

Example

LISTVIEW statement IMPROVED

Purpose Manipulate a LISTVIEW control in order to set/retrieve data.

Syntax

```
LISTVIEW DELETE COLUMN hDlg, id&, col&
LISTVIEW DELETE ITEM hDlg, id&, item&
LISTVIEW FIND hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIT CONTENT hDlg, id&, col&
LISTVIEW FIT HEADER hDlg, id&, col&
LISTVIEW GET COLUMN hDlg, id&, col& TO datav&
LISTVIEW GET COUNT hDlg, id& TO datav&
LISTVIEW GET HEADER hDlg, id&, col& TO txtv$
LISTVIEW GET HEADERID hDlg, id& TO hLV, idv&
LISTVIEW GET MODE hDlg, id& TO datav&
LISTVIEW GET SELCOUNT hDlg, id& TO datav&
LISTVIEW GET SELECT hDlg, id& [, item&] TO datav&
LISTVIEW GET STATE hDlg, id&, item&, col& TO datav&
LISTVIEW GET STYLEXX hDlg, id& TO datav&
LISTVIEW GET TEXT hDlg, id&, item&, col& TO txtv$
LISTVIEW GET USER hDlg, id&, item& TO datav&
LISTVIEW INSERT COLUMN hDlg, id&, col&, StrExpr, ColWidth&, format&
LISTVIEW INSERT ITEM hDlg, id&, item&, image&, StrExpr
LISTVIEW RESET hDlg, id&
LISTVIEW SELECT hDlg, id&, item& [, col&]
LISTVIEW SET COLUMN hDlg, id&, col&, NumExpr
LISTVIEW SET HEADER hDlg, id&, col&, StrExpr
LISTVIEW SET IMAGE hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGE2 hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGELIST hDlg, id&, hLst, NumExpr
LISTVIEW SET MODE hDlg, id&, NumExpr
LISTVIEW SET OVERLAY hDlg, id&, item&, NumExpr
LISTVIEW SET STYLEXX hDlg, id&, NumExpr
LISTVIEW SET TEXT hDlg, id&, item&, col&, StrExpr
LISTVIEW SET USER hDlg, id&, item&, NumExpr
LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg	Handle of the dialog that owns the ListView.
hLst	Handle of the ImageList to be used for graphical items.
hLV	Handle of the ListView Control.
id&	The control identifier assigned with CONTROL ADD LISTVIEW.

item&	A data item number. First=1, second=2...
col&	A vertical column number. First=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks

There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0	Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either

dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker

%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg, id&, col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView

control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

Example

LISTVIEW statement IMPROVED

Purpose Manipulate a LISTVIEW control in order to set/retrieve data.

Syntax

```
LISTVIEW DELETE COLUMN hDlg, id&, col&
LISTVIEW DELETE ITEM hDlg, id&, item&
LISTVIEW FIND hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIT CONTENT hDlg, id&, col&
LISTVIEW FIT HEADER hDlg, id&, col&
LISTVIEW GET COLUMN hDlg, id&, col& TO datav&
LISTVIEW GET COUNT hDlg, id& TO datav&
LISTVIEW GET HEADER hDlg, id&, col& TO txtv$
LISTVIEW GET HEADERID hDlg, id& TO hLV, idv&
LISTVIEW GET MODE hDlg, id& TO datav&
LISTVIEW GET SELCOUNT hDlg, id& TO datav&
LISTVIEW GET SELECT hDlg, id& [, item&] TO datav&
LISTVIEW GET STATE hDlg, id&, item&, col& TO datav&
LISTVIEW GET STYLEXX hDlg, id& TO datav&
LISTVIEW GET TEXT hDlg, id&, item&, col& TO txtv$
LISTVIEW GET USER hDlg, id&, item& TO datav&
LISTVIEW INSERT COLUMN hDlg, id&, col&, StrExpr, ColWidth&, format&
LISTVIEW INSERT ITEM hDlg, id&, item&, image&, StrExpr
LISTVIEW RESET hDlg, id&
LISTVIEW SELECT hDlg, id&, item& [, col&]
```

LISTVIEW SET COLUMN ***hDlg, id&, col&, NumExpr***
LISTVIEW SET HEADER ***hDlg, id&, col&, StrExpr***
LISTVIEW SET IMAGE ***hDlg, id&, item&, NumExpr***
LISTVIEW SET IMAGE2 ***hDlg, id&, item&, NumExpr***
LISTVIEW SET IMAGELIST ***hDlg, id&, hLst, NumExpr***
LISTVIEW SET MODE ***hDlg, id&, NumExpr***
LISTVIEW SET OVERLAY ***hDlg, id&, item&, NumExpr***
LISTVIEW SET STYLEXX ***hDlg, id&, NumExpr***
LISTVIEW SET TEXT ***hDlg, id&, item&, col&, StrExpr***
LISTVIEW SET USER ***hDlg, id&, item&, NumExpr***
LISTVIEW SORT ***hDlg, id&, col&* [, *options*...]**
LISTVIEW UNSELECT ***hDlg, id&, item&*, [*col&*]**
LISTVIEW VISIBLE ***hDlg, id&, item&***

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the

unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number

(1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg, id&, item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg, id&, col&, StrExpr, ColWidth&, format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&*

specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
% LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode

% LVS_EX_ONECLICKACTIVATE	Notification sent on single click
% LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg, id&, col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format:

	, , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW VISIBLE ***hDlg, id&, item&***

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon

IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is

assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg, id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg, id&, item&, col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg, id&, item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg, id&, col&, StrExpr, ColWidth&, format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for

the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg*, *id&*, *NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg*, *id&*, *item&*, *col&*, *StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe

the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

StrExpr	A string expression passed as a parameter.
txtv$	A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg, id&, col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg, id&, item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of

the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are

currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted

from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use

LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg, id&, item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW SET USER hDlg, id&, item&, NumExpr
```

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]
LISTVIEW UNSELECT *hDlg*, *id&*, *item&*, [*col&*]
LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg, id&, col&, StrExpr, ColWidth&, format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary

image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg*, *id&*, *hLst*, *NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg*, *id&*, *NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg*, *id&*, *item&*, *NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg*, *id&*, *NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text

%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg*, *id&*, *item&*, *col&*, *StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg, id&, item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg, id&, item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

Example

LISTVIEW statement IMPROVED

Purpose Manipulate a LISTVIEW control in order to set/retrieve data.

Syntax

```
LISTVIEW DELETE COLUMN hDlg, id&, col&
LISTVIEW DELETE ITEM hDlg, id&, item&
LISTVIEW FIND hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIT CONTENT hDlg, id&, col&
LISTVIEW FIT HEADER hDlg, id&, col&
LISTVIEW GET COLUMN hDlg, id&, col& TO datav&
LISTVIEW GET COUNT hDlg, id& TO datav&
LISTVIEW GET HEADER hDlg, id&, col& TO txtv$
LISTVIEW GET HEADERID hDlg, id& TO hLV, idv&
LISTVIEW GET MODE hDlg, id& TO datav&
LISTVIEW GET SELCOUNT hDlg, id& TO datav&
LISTVIEW GET SELECT hDlg, id& [, item&] TO datav&
LISTVIEW GET STATE hDlg, id&, item&, col& TO datav&
LISTVIEW GET STYLEXX hDlg, id& TO datav&
LISTVIEW GET TEXT hDlg, id&, item&, col& TO txtv$
LISTVIEW GET USER hDlg, id&, item& TO datav&
```

```
LISTVIEW INSERT COLUMN hDlg, id&, col&, StrExpr, ColWidth&, format&
LISTVIEW INSERT ITEM hDlg, id&, item&, image&, StrExpr
LISTVIEW RESET hDlg, id&
LISTVIEW SELECT hDlg, id&, item& [, col&]
LISTVIEW SET COLUMN hDlg, id&, col&, NumExpr
LISTVIEW SET HEADER hDlg, id&, col&, StrExpr
LISTVIEW SET IMAGE hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGE2 hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGELIST hDlg, id&, hLst, NumExpr
LISTVIEW SET MODE hDlg, id&, NumExpr
LISTVIEW SET OVERLAY hDlg, id&, item&, NumExpr
LISTVIEW SET STYLEXX hDlg, id&, NumExpr
LISTVIEW SET TEXT hDlg, id&, item&, col&, StrExpr
LISTVIEW SET USER hDlg, id&, item&, NumExpr
LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg	Handle of the dialog that owns the ListView.
hLst	Handle of the ImageList to be used for graphical items.
hLV	Handle of the ListView Control.
id&	The control identifier assigned with CONTROL ADD LISTVIEW.
item&	A data item number. First=1, second=2...
col&	A vertical column number. First=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks

There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 — Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 — Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 — Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 — List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data

item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg, id&, item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg, id&, col&, StrExpr, ColWidth&, format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection

%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg, id&, col&* [, *options...*]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string

NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW statement IMPROVED

Purpose Manipulate a LISTVIEW control in order to set/retrieve data.

Syntax

```
LISTVIEW DELETE COLUMN hDlg, id&, col&
LISTVIEW DELETE ITEM hDlg, id&, item&
```

```
LISTVIEW FIND hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIT CONTENT hDlg, id&, col&
LISTVIEW FIT HEADER hDlg, id&, col&
LISTVIEW GET COLUMN hDlg, id&, col& TO datav&
LISTVIEW GET COUNT hDlg, id& TO datav&
LISTVIEW GET HEADER hDlg, id&, col& TO txtv$
LISTVIEW GET HEADERID hDlg, id& TO hLV, idv&
LISTVIEW GET MODE hDlg, id& TO datav&
LISTVIEW GET SELCOUNT hDlg, id& TO datav&
LISTVIEW GET SELECT hDlg, id& [, item&] TO datav&
LISTVIEW GET STATE hDlg, id&, item&, col& TO datav&
LISTVIEW GET STYLEXX hDlg, id& TO datav&
LISTVIEW GET TEXT hDlg, id&, item&, col& TO txtv$
LISTVIEW GET USER hDlg, id&, item& TO datav&
LISTVIEW INSERT COLUMN hDlg, id&, col&, StrExpr, ColWidth&, format&
LISTVIEW INSERT ITEM hDlg, id&, item&, image&, StrExpr
LISTVIEW RESET hDlg, id&
LISTVIEW SELECT hDlg, id&, item& [, col&]
LISTVIEW SET COLUMN hDlg, id&, col&, NumExpr
LISTVIEW SET HEADER hDlg, id&, col&, StrExpr
LISTVIEW SET IMAGE hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGE2 hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGELIST hDlg, id&, hLst, NumExpr
LISTVIEW SET MODE hDlg, id&, NumExpr
LISTVIEW SET OVERLAY hDlg, id&, item&, NumExpr
LISTVIEW SET STYLEXX hDlg, id&, NumExpr
LISTVIEW SET TEXT hDlg, id&, item&, col&, StrExpr
LISTVIEW SET USER hDlg, id&, item&, NumExpr
LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg	Handle of the dialog that owns the ListView.
hLst	Handle of the ImageList to be used for graphical items.
hLV	Handle of the ListView Control.
id&	The control identifier assigned with CONTROL ADD LISTVIEW.
item&	A data item number. First=1, second=2...
col&	A vertical column number. First=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks

There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0	Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in

each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg, id&, col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg, id&, item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is

found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg*, *id&*, *item&* [, *col&*]

The string data item specified by *item&/col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&/col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg*, *id&*, *col&*, *NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg*, *id&*, *col&*, *StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg*, *id&*, *item&*, *NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg*, *id&*, *item&*, *NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg*, *id&*, *hLst*, *NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg*, *id&*, *NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg*, *id&*, *item&*, *NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg, id&, col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks

There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0	Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg, id&, col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg, id&, item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins

with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg, id&, col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg, id&, col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg, id&* TO *hLV, idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg, id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg, id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg, id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not

a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons

%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the

optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW SET MODE hDlg, id&, NumExpr
LISTVIEW SET OVERLAY hDlg, id&, item&, NumExpr
```

LISTVIEW SET STYLEXX ***hDlg, id&, NumExpr***
LISTVIEW SET TEXT ***hDlg, id&, item&, col&, StrExpr***
LISTVIEW SET USER ***hDlg, id&, item&, NumExpr***
LISTVIEW SORT ***hDlg, id&, col&*** **[,** ***options*****...]**
LISTVIEW UNSELECT ***hDlg, id&, item&,*** **[*****col&*****]**
LISTVIEW VISIBLE ***hDlg, id&, item&***

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column

numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg, id&, col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg, id&, item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg, id&, col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable

specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg, id&, col&, StrExpr, ColWidth&, format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&/col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&/col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text

%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg*, *id&*, *item&*, *col&*, *StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and

	delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one

item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*)

is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This

special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg*, *id&*, *item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg*, *id&*, *col&*, *NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If

NumExpr is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg, id&, col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.

UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to

multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which

exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg, id&, col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg, id&, col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg, id&* TO *hLV, idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg, id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg, id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg, id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to

facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
% LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
% LVS_EX_ONECLICKACTIVATE	Notification sent on single click
% LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user

value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either

dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker

%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg, id&, col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView

control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the

unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number

(1=first, 2=second, etc.).

<u>LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*</u>

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

<u>LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*</u>

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

<u>LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*</u>

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

<u>LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*</u>

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

<u>LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*</u>

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

<u>LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*</u>

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

<u>LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*</u>

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

<u>LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*</u>

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

<u>LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*</u>

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg*, *id&*, *item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg*, *id&*, *col&*, *NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg*, *id&*, *col&*, *StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&*

specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
% LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode

%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg*, *id&*, *item&*, *col&*, *StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format:

	, , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg, id&, item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg, id&, item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon

IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is

assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg, id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg, id&, item&, col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg, id&, item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg, id&, col&, StrExpr, ColWidth&, format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for

the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg*, *id&*, *NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg*, *id&*, *item&*, *col&*, *StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe

the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the [ASCII](#) value of each byte, so that case is significant. Comparison is limited to the first 255 [bytes](#) of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0	Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of

the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg, id&, col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg, id&, col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg, id&* TO *hLV, idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg, id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg, id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are

currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted

from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use

LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg, id&, item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

```

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]
LISTVIEW UNSELECT *hDlg*, *id&*, *item&*, [*col&*]
LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

hDlg Handle of the dialog that owns the ListView.

hLst Handle of the ImageList to be used for graphical items.

hLV Handle of the ListView Control.

id& The control identifier assigned with CONTROL ADD LISTVIEW.

item& A data item number. First=1, second=2...

col& A vertical column number. First=1, second=2...

NumExpr A

expression passed as a parameter.

StrExpr A string expression passed as a parameter.

txtv$ A

variable to which result text is assigned.

datav& A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0 Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 1 Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg, id&, col&, StrExpr, ColWidth&, format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg, id&, item&, image&, StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg, id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg, id&, item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg, id&, col&, NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary

image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text

%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg, id&, col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

Example

LISTVIEW statement IMPROVED

Purpose Manipulate a LISTVIEW control in order to set/retrieve data.

Syntax

```
LISTVIEW DELETE COLUMN hDlg, id&, col&
LISTVIEW DELETE ITEM hDlg, id&, item&
LISTVIEW FIND hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIND EXACT hDlg, id&, item&, StrExpr TO datav&
LISTVIEW FIT CONTENT hDlg, id&, col&
LISTVIEW FIT HEADER hDlg, id&, col&
LISTVIEW GET COLUMN hDlg, id&, col& TO datav&
LISTVIEW GET COUNT hDlg, id& TO datav&
LISTVIEW GET HEADER hDlg, id&, col& TO txtv$
LISTVIEW GET HEADERID hDlg, id& TO hLV, idv&
LISTVIEW GET MODE hDlg, id& TO datav&
LISTVIEW GET SELCOUNT hDlg, id& TO datav&
LISTVIEW GET SELECT hDlg, id& [, item&] TO datav&
LISTVIEW GET STATE hDlg, id&, item&, col& TO datav&
LISTVIEW GET STYLEXX hDlg, id& TO datav&
LISTVIEW GET TEXT hDlg, id&, item&, col& TO txtv$
LISTVIEW GET USER hDlg, id&, item& TO datav&
```

```
LISTVIEW INSERT COLUMN hDlg, id&, col&, StrExpr, ColWidth&, format&
LISTVIEW INSERT ITEM hDlg, id&, item&, image&, StrExpr
LISTVIEW RESET hDlg, id&
LISTVIEW SELECT hDlg, id&, item& [, col&]
LISTVIEW SET COLUMN hDlg, id&, col&, NumExpr
LISTVIEW SET HEADER hDlg, id&, col&, StrExpr
LISTVIEW SET IMAGE hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGE2 hDlg, id&, item&, NumExpr
LISTVIEW SET IMAGELIST hDlg, id&, hLst, NumExpr
LISTVIEW SET MODE hDlg, id&, NumExpr
LISTVIEW SET OVERLAY hDlg, id&, item&, NumExpr
LISTVIEW SET STYLEXX hDlg, id&, NumExpr
LISTVIEW SET TEXT hDlg, id&, item&, col&, StrExpr
LISTVIEW SET USER hDlg, id&, item&, NumExpr
LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg	Handle of the dialog that owns the ListView.
hLst	Handle of the ImageList to be used for graphical items.
hLV	Handle of the ListView Control.
id&	The control identifier assigned with CONTROL ADD LISTVIEW.
item&	A data item number. First=1, second=2...
col&	A vertical column number. First=1, second=2...
NumExpr	A expression passed as a parameter.
StrExpr	A string expression passed as a parameter.
txtv$	A variable to which result text is assigned.
datav&	A long integer variable to which result data is assigned.

Remarks There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0	Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data

item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg*, *id&*, *col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg*, *id&*, *col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg*, *id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg*, *id&*, *col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg*, *id&* TO *hLV*, *idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg*, *id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg*, *id&*, *item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg*, *id&*, *col&*, *NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg, id&, col&, StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg, id&, item&, NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg, id&, hLst, NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection

%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg, id&, item&, NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg, id&, col&* [, *options...*]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string

NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

LISTVIEW SET STYLEXX hDlg, id&, NumExpr
LISTVIEW SET TEXT hDlg, id&, item&, col&, StrExpr
LISTVIEW SET USER hDlg, id&, item&, NumExpr
LISTVIEW SORT hDlg, id&, col& [, options...]
LISTVIEW UNSELECT hDlg, id&, item&, [col&]
LISTVIEW VISIBLE hDlg, id&, item&
```

hDlg — Handle of the dialog that owns the ListView.

hLst — Handle of the ImageList to be used for graphical items.

hLV — Handle of the ListView Control.

id& — The control identifier assigned with CONTROL ADD LISTVIEW.

item& — A data item number. First=1, second=2...

col& — A vertical column number. First=1, second=2...

NumExpr — A

expression passed as a parameter.

StrExpr — A string expression passed as a parameter.

txtv$ — A

variable to which result text is assigned.

datav& — A long integer variable to which result data is assigned.

Remarks — There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

- Mode 0 — Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
- Mode 1 — Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in

each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 2 Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

Mode 3 List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg, id&, col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg, id&, item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is

found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg, id&, col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg, id&, col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg, id&* TO *hLV, idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg, id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg, id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg, id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg*, *id&*, *item&* [, *col&*]

The string data item specified by *item&/col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&/col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg*, *id&*, *col&*, *NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg*, *id&*, *col&*, *StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg*, *id&*, *item&*, *NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg*, *id&*, *item&*, *NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg*, *id&*, *hLst*, *NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons
%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg*, *id&*, *NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg*, *id&*, *item&*, *NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg*, *id&*, *NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg*, *id&*, *item&*, *col&*, *StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg*, *id&*, *item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.

datav&	A long integer variable to which result data is assigned.

Remarks

There are 4 general display modes available with a LISTVIEW control. The initial display mode is established at the time the control is created, as a part of the control style parameter. It may be changed from time to time with LISTVIEW SET MODE.

Mode 0	Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 1	Report Mode - String data items are displayed as a list, top to bottom, one item per line. The control may have one or more columns, with header text to describe each of them. Additional sub-items may be displayed in each column, by specifying a column number greater than one. This is the most frequently used ListView mode, and the default mode if not specified at the time the control is created. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 2	Small Icon Mode - String data items are displayed left to right, wrapped to multiple lines as necessary. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.
Mode 3	List Mode - String data items are displayed as a list, top to bottom, one item per line. This mode is very similar in appearance to a standard LISTBOX control. In this mode, it's often convenient to think of the item number as a row number. If a small icon IMAGELIST is attached to the LISTVIEW control, images from that list are displayed with each data item.

In all of the following descriptions, the LISTVIEW control which is the subject of the statement is identified by the handle of the dialog that owns the LISTVIEW (*hDlg*), and the unique control identifier (*id&*) you gave it upon creation in CONTROL ADD LISTVIEW.

Each data item (or sub-item) is referenced by a combination of its item number (*item&*) and its column number (*col&*). A primary data item always has a column number of 1, while sub-items always have a column number greater than 1. Sub-items are only displayed in Report Mode. In all other display modes, they are hidden from view.

It's important to note that both primary item numbers (*item&*) and sub-item column numbers (*col&*) start at 1. The first=1, the second=2, and so forth.

LISTVIEW DELETE COLUMN *hDlg*, *id&*, *col&*

The column specified by *col&*, including its associated header text (if any), is deleted from the LISTVIEW control. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). Column one of a list-view control cannot be deleted. If you must delete column one, insert a zero length dummy column one and delete column two and above. This is a limitation of the Microsoft Windows Listview control and not a PowerBASIC limitation.

LISTVIEW DELETE ITEM *hDlg*, *id&*, *item&*

The data item specified by *item&* is deleted from the LISTVIEW control. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIND *hDlg*, *id&*, *item&*, *StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which begins

with the data in *StrExpr*, regardless of any characters which follow. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIND EXACT *hDlg, id&, item&, StrExpr* TO *datav&*

Strings in the first column of a LISTVIEW are searched to find the first string which exactly matches the data in *StrExpr*. Comparisons are not case-sensitive. Strings are searched beginning with the string specified by *item&*, and ending with the last string in the LISTVIEW. Searching does not wrap to the beginning of the list. The row number (*item&*) is indexed to 1 (1=first, 2=second, etc.). To search the entire LISTVIEW starting with the first string, *item&* should be set to one (1). If a matching string is found, the index value of the match is assigned to the variable specified by *datav&*. If no match is found, the value zero (0) is assigned to it.

LISTVIEW FIT CONTENT *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the data items displayed in that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.).

LISTVIEW FIT HEADER *hDlg, id&, col&*

The width of the column specified by *col&* is adjusted to fit the width of the rows displayed in that column, and the header text at the top of that column. The column number (*col&*) is indexed to 1 (1=first, 2=second, etc.). If the specified column is the last column, its width is set to fill the remaining width of the list-view control.

LISTVIEW GET COLUMN *hDlg, id&, col&* TO *datav&*

The width of the designated column is retrieved from the ListView and assigned to the variable specified by *datav&*. The width is specified in either pixels or dialog units, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET COUNT *hDlg, id&* TO *datav&*

The number of rows in the LISTVIEW is retrieved, and assigned to the long integer variable specified by *datav&*.

LISTVIEW GET HEADER *hDlg, id&, col&* TO *txtv$*

Column header text is retrieved from the LISTVIEW and assigned to the string variable specified by *txtv$*. The value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW GET HEADERID *hDlg, id&* TO *hLV, idv&*

The handle of the LISTVIEW control and the ID of HEADER control (a child of the LISTVIEW) are retrieved and assigned to the variables represented by *hLV* and *idv&* respectively. These two items may then be used with the HEADER statement for advanced handling of the header control which is embedded in the LISTVIEW.

LISTVIEW GET MODE *hDlg, id&* TO *datav&*

The display mode of the specified LISTVIEW control is retrieved and assigned to the variable designated by *datav&*. Possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW GET SELCOUNT *hDlg*, *id&* TO *datav&*

The LISTVIEW is interrogated to determine the number of primary data items which are currently selected. This count is assigned to the long integer variable specified by *datav&*. To determine the count of sub-items selections, you must execute LISTVIEW GET STATE on every active sub-item.

LISTVIEW GET SELECT *hDlg*, *id&* [, *item&*] TO *datav&*

The LISTVIEW is interrogated to determine the next primary data item which is currently selected. The parameter *item&* specifies the starting item number for the search, to facilitate retrieving multiple selected items. To start at the beginning, use an *item&* of one (1), or just omit that parameter. The selected item number is assigned to the long integer variable specified by *datav&*. If no selected items are found, the value zero (0) is returned. To find selected sub-items, you must execute LISTVIEW GET STATE on remaining active sub-items.

LISTVIEW GET STATE *hDlg*, *id&*, *item&*, *col&* TO *datav&*

A data item is tested to see if it is currently selected. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.). If the item is selected, -1 (true) is assigned to the variable specified by *datav&*. Otherwise, 0 (false) is assigned to it.

LISTVIEW GET STYLEXX *hDlg*, *id&* TO *datav&*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement retrieves the current setting of this special extended style, and assigns it to the long integer variable specified by *datav&*. A list of the available extended styles can be found under LISTVIEW SET STYLEXX. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW.

LISTVIEW GET TEXT *hDlg*, *id&*, *item&*, *col&* TO *txtv$*

A string data item is retrieved from the LISTVIEW control and assigned to the string variable specified by *txtv$*. The values of *item&*/*col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW GET USER *hDlg*, *id&*, *item&* TO *datav&*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is requested, 1 for the first row, 2 for the second row, etc. The returned user value is assigned to the long integer variable specified by *datav&*. LISTVIEW user values are assigned with the LISTVIEW SET USER statement. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW INSERT COLUMN *hDlg*, *id&*, *col&*, *StrExpr*, *ColWidth&*, *format&*

A new vertical column is defined for Report Mode of this LISTVIEW control. The value *col&* specifies the column number (1=first, 2=second, etc.). *StrExpr* describes the text name of the column header. The value *ColWidth&* specifies the width of the column in either dialog units or pixels, depending upon which was specified at creation. The value *format&* describes the format and justification of the text: 0=left, 1=right, 2=center. Column 1 is always left-justified, regardless of what is requested here. When inserting a new column 1, the contents of the original column 1 are copied to the new column 1. This only occurs when inserting a new left most column, when inserting other columns, no data is copied to the new column. This is a limitation of the Microsoft Windows Listview control and not

a PowerBASIC limitation.

LISTVIEW INSERT ITEM *hDlg*, *id&*, *item&*, *image&*, *StrExpr*

A new row is added to this LISTVIEW control. The value *item&* specifies the row number (1=first, 2=second, etc.), and *StrExpr* tells the text to be displayed in the first column. The remaining columns are empty, but you can fill them by executing LISTVIEW SET TEXT. If an IMAGELIST has been attached to this control, the parameter *image&* specifies which image should be displayed (1=first, 2=second, etc.). If no image is needed, the value 0 should be used.

LISTVIEW RESET *hDlg*, *id&*

All data items are deleted from the specified LISTVIEW control. Any columns, and their associated headers, which may have been defined for Report Display mode are retained without change.

LISTVIEW SELECT *hDlg*, *id&*, *item&* [, *col&*]

The string data item specified by *item&*/*col&* is chosen as selected text for the LISTVIEW control and the item is highlighted. The values of *item&*/*col&* = 1 for the first item, 2 for the second item, etc. If the optional parameter *col&* is not given, the default value of 1 is used to select the primary data item.

LISTVIEW SET COLUMN *hDlg*, *id&*, *col&*, *NumExpr*

The width of a LISTVIEW column is changed to that designated by the *NumExpr*. The value is specified in either dialog units or pixels, depending upon which was used at creation. The value *col&* specifies the column number (1=first, 2=second, etc.). If *NumExpr* is -1, then the column width is adjusted to fit the data items in that column. If *NumExpr* is -2, the column width is adjusted to fit both the data items and the header text. These options are functionally identical to LISTVIEW FIT CONTENT and LISTVIEW FIT HEADER.

LISTVIEW SET HEADER *hDlg*, *id&*, *col&*, *StrExpr*

New column header text is displayed above the specified column on the LISTVIEW control. The string expression *StrExpr* specifies the new header text, while the value *col&* specifies the column number (1=first, 2=second, etc.).

LISTVIEW SET IMAGE *hDlg*, *id&*, *item&*, *NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed next to the item specified by *item&*. If no IMAGELIST is attached to the LISTVIEW, nothing is displayed.

LISTVIEW SET IMAGE2 *hDlg*, *id&*, *item&*, *NumExpr*

The image specified by *NumExpr* (1=first, 2=second, etc.) is displayed as a secondary "status" image next to the primary image. If *NumExpr* evaluates to zero, no secondary image is displayed. A secondary image is usually used to specify item status, with an image such as a check mark. Secondary images are generally not displayed in either of the icon modes. If no Status Image List is attached to the LISTVIEW (using the LISTVIEW IMAGELIST statement), nothing is displayed. A maximum of 15 status images are supported, so *NumExpr* must evaluate in the range of 1-15.

LISTVIEW SET IMAGELIST *hDlg*, *id&*, *hLst*, *NumExpr*

The IMAGELIST specified by *hLst* is attached to this LISTVIEW control. The value of *NumExpr* specifies the type of IMAGELIST:

%LVSIL_NORMAL	Large icons
%LVSIL_SMALL	Small icons

%LVSIL_STATE	Status images

Up to three IMAGELIST structures may be attached to each LISTVIEW to display images as needed with each data item. Depending upon the mode in effect, icons are extracted from either the large icon or small icon list for that purpose. If a status image list is also attached, the LISTVIEW SET IMAGE2 statement may be used to display a secondary image. When the LISTVIEW control is destroyed, any attached IMAGELIST is automatically destroyed unless the %LVS_SHAREIMAGELISTS style was specified at the time the LISTVIEW was created.

LISTVIEW SET MODE *hDlg, id&, NumrExpr*

The display mode of the specified LISTVIEW control is changed to that designated by the value of *NumExpr*. The possible mode values are 0=icon mode, 1=report mode, 2=small icon mode, 3=list mode.

LISTVIEW SET OVERLAY *hDlg, id&, item&, NumExpr*

The overlay image specified by *NumExpr* (1=first, 2=second, etc.) is displayed on top of the image specified by *item&*. If *NumExpr* evaluates to zero, or if no IMAGELIST is attached to the LISTVIEW, no overlay is displayed.

LISTVIEW SET STYLEXX *hDlg, id&, NumExpr*

ListView controls offer a number of optional additional style attributes which are unique and specific to a ListView. This statement allows you to alter the current setting of this special extended style. This special extended style is named STYLEXX to distinguish it from the primary style and extended style specified in CONTROL ADD LISTVIEW. *NumExpr* defines the new style from any combination of the following extended styles:

%LVS_EX_GRIDLINES	Grid lines added in report mode
%LVS_EX_SUBITEMIMAGES	Icons added to sub-items in report mode
%LVS_EX_CHECKBOXES	Enables checkboxes to items
%LVS_EX_TRACKSELECT	Enables hot track selection
%LVS_EX_HEADERDRAGDROP	Enables drag-drop reordering of columns in report mode
%LVS_EX_FULLROWSELECT	Selection highlights full row in report mode
%LVS_EX_ONECLICKACTIVATE	Notification sent on single click
%LVS_EX_TWOCLICKACTIVATE	Notification sent on double click
%LVS_EX_FLATSB	Enables flat scroll bars
%LVS_EX_REGIONAL	Sets ListView region to icons and text
%LVS_EX_INFOTIP	Listview does InfoTips for you
%LVS_EX_UNDERLINEHOT	Hot items have underlined text
%LVS_EX_UNDERLINECOLD	Non-hot items have underlined text
%LVS_EX_MULTIWORKAREAS	Will not auto-arrange until work areas defined
%LVS_EX_LABELTIP	Listview unfolds partly hidden labels
%LVS_EX_BORDERSELECT	Border selection style instead of highlight
%LVS_EX_DOUBLEBUFFER	Paints via double-buffering and reduces flicker
%LVS_EX_HIDELABELS	Hides labels in Icon and Small Icon mode
%LVS_EX_SINGLEROW	Display a single row
%LVS_EX_SNAPTOGRID	Icons automatically snap to grid
%LVS_EX_SIMPLESELECT	Changes overlay rendering to top right

LISTVIEW SET TEXT *hDlg, id&, item&, col&, StrExpr*

The text, if any, for the specified data item is replaced by the new text in *StrExpr*. You must keep in mind that this statement does not create a new item (horizontal row), but changes existing text, if any, to new text. To create a new data item (horizontal row), use LISTVIEW INSERT ITEM instead. The values of *item&/col&* specify the position of the data item (1=first, 2=second, etc.).

LISTVIEW SET USER *hDlg*, *id&*, *item&*, *NumExpr*

Each row in a LISTVIEW may have a long integer user value associated with it at the discretion of the programmer. This user value is assigned with LISTVIEW SET USER, and retrieved with LISTVIEW GET USER. The numeric value *item&* specifies which user value is to be accessed, 1 for the first item, 2 for the second item, etc. The value specified by *NumExpr* is saved for later retrieval. In addition to these LISTVIEW user values, every DDT control offers an additional eight user values which can be accessed with CONTROL GET USER and CONTROL SET USER.

LISTVIEW SORT *hDlg*, *id&*, *col&* [, *options*...]

All of the items in a LISTVIEW are sorted, based upon the value of the data in a particular column. The column number (*col&*) is specified as 1 for the first column, 2 for the second column, etc. The options are one or more comma-delimited parameters which describe the sequence and the nature of the data in the sort-key column:

ASCEND	The items are arranged in ascending sequence.
DESCEND	The items are arranged in descending sequence.
ALPHANUM	The items consist of alphanumeric data. They are sequenced based upon the ASCII value of each byte, so that case is significant. Comparison is limited to the first 255 bytes of each string.
UCASE	The items consist of alphanumeric data. The case of each alphabetic character is not significant. This is accomplished by treating all alphabetic characters as upper case letters. Comparison is limited to the first 255 bytes of each string
NUMERIC	The items start with numeric data, and evaluation is stopped at the first non-numeric character. If numeric characters are not found, the value is assumed to be zero (0). This data may be in any supported PowerBASIC format: , , scientific notation, radix format, etc.
MMDDYYYY	A date in the format mm/dd/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
DDMMYYYY	A date in the format dd/mm/yyyy which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYMMDD	A date in the format yyyy/mm/dd which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.
YYYYDDMM	A date in the format yyyy/dd/mm which is exactly ten bytes in length. Leading zeros may be replaced by spaces, and delimiters may be any character.

It is important to note that Windows may overwrite USER data when sorting your ListView control. You should avoid the use of the LISTVIEW GET USER and LISTVIEW SET USER statements if you may also execute a LISTVIEW SORT on the same control.

LISTVIEW UNSELECT *hDlg*, *id&*, *item&* [, *col&*]

The string value specified by item&/col& is set to an unselected state for the LISTVIEW control. The values of item&/col& = 1 for the first item, 2 for the second item, etc. If the

optional parameter *col&* is not given, the default value of 1 is used to unselect the primary data item.

LISTVIEW VISIBLE *hDlg, id&, item&*

A row is scrolled, if necessary, to ensure that the data specified by *item&* is visible. The value of *item&* = 1 for the first row, 2 for the second row, etc.

Restrictions Under Windows 95/98/ME, a ListView is limited to 32,767 items. In all versions of Windows, the actual string data contained by the ListView is limited only by available memory.
